Product Documentation

About Your Switch Manual Set

The switch manual set includes the following documentation:

- *Read Me First*—a printed guide shipped with your switch. Provides software update information, product notes, and other information.
- *Installation and Getting Started Guide*—a printed guide shipped with your switch. This guide explains how to prepare for and perform the physical installation and connect the switch to your network.
- *Management and Configuration Guide*—a PDF on the ProCurve Networking Web Site that describes how to configure, manage, and monitor basic switch operation.
- *Advanced Traffic Management Guide*—a PDF on the ProCurve Networking Web Site that explains how to configure traffic management features such as VLANs, MSTP, and QoS.
- *Multicast and Routing Guide*—a PDF on the ProCurve Networking Web Site that explains how to configure IGMP and IP routing.
- *Access Security Guide*—a PDF on the ProCurve Networking Web Site that explains how to configure access security features and user authentication on the switch.
- *Release Notes*—posted on the ProCurve Networking Web Site to provide information on software updates. The release notes describe new features, fixes, and enhancements that become available between revisions of the main product guide.

Note

For the latest version of all ProCurve switch documentation, including Release Notes covering recently added features, visit the ProCurve Networking Web Site at **www.procurve.com**, click on **Technical support**, and then click on **Product manuals (all)**.

Feature Index

For the manual set supporting your switch model, the following feature index indicates which manual to consult for information on a given software feature.

Feature	Management and Configuration	Advanced Traffic Management	Multicast and Routing	Access Security Guide
802.1Q VLAN Tagging		X		
802.1p Priority	X			
802.1X Port-Based Authentication				X

Introduction

This *Management and Configuration Guide* is intended for use with the following switches:

- ProCurve Switch 2900-24G
- ProCurve Switch 2900-48G

This guide describes how to use the command line interface (CLI), Menu interface, and web browser to configure, manage, monitor, and troubleshoot switch operation.

For an overview of other product documentation for the above switches, refer to “*Product Documentation*” on page ix.

You can download documentation from the ProCurve Networking Web Site, **www.procurve.com**.

Caution

Use only the supported genuine ProCurve mini-GBICs with your switch. Non-ProCurve mini-GBICs are not supported.

Conventions

This guide uses the following conventions for command syntax and displayed information.

Feature Descriptions by Model

In cases where a software feature is not available in all of the switch models covered by this guide, the section heading specifically indicates which product or product series offer the feature.

For example, (the switch is highlighted here in ***bold italics***):

“QoS Pass-Through Mode on the ***Switch 2900***”.

Command Syntax Statements

Syntax: ip default-gateway < ip-addr >

Syntax: show interfaces [*port-list*]

- Vertical bars (|) separate alternative, mutually exclusive elements.
- Square brackets ([]) indicate optional elements.
- Braces (< >) enclose required elements.
- Braces within square brackets ([< >]) indicate a required element within an optional choice.
- Boldface indicates use of a CLI command, part of a CLI command syntax, or other displayed element in general text. For example:
 “Use the **copy tftp** command to download the key from a TFTP server.”
- Italics indicate variables for which you must supply a value when executing the command. For example, in this command syntax, you must provide one or more port numbers:

Syntax: aaa port-access authenticator < *port-list* >

Command Prompts

In the default configuration, your switch displays a CLI prompt similar to the following:

```
ProCurve 2900-24G#
```

To simplify recognition, this guide uses **ProCurve** to represent command prompts for all models. For example:

```
ProCurve#
```

(You can use the **hostname** command to change the text in the CLI prompt.)

Screen Simulations

Displayed Text. Figures containing simulated screen text and command output look like this:

```
ProCurve> show version
Image stamp:   /sw/code/build/info
               March 1, 2006 13:43:13
               T.11.01
               139

ProCurve>
```

Figure 1-1. Example of a Figure Showing a Simulated Screen

In some cases, brief command-output sequences appear without figure identification. For example:

```
ProCurve(config)# clear public-key
ProCurve(config)# show ip client-public-key
show_client_public_key: cannot stat keyfile
```

Port Identity Examples

This guide describes software applicable to both chassis-based and stackable ProCurve switches. Where port identities are needed in an example, this guide uses the chassis-based port identity system, such as “A1”, “B3-B5”, “C7”, etc. However, unless otherwise noted, such examples apply equally to the stackable switches, which typically use only numbers, such as “1”, “3-5”, “15”, etc. for port identities.

Configuration and Operation Examples

Unless otherwise noted, examples using a particular switch model apply to all switch models covered by this guide.

Keys

Simulations of actual keys use a bold, sans-serif typeface with square brackets. For example, the Tab key appears as **[Tab]** and the “Y” key appears as **[Y]**.

Sources for More Information

For additional information about switch operation and features not covered in this guide, consult the following sources:

- **Feature Index**—For information on which product manual to consult for a given software feature, refer to the “Feature Index” on page x.

Note

For the latest version of all ProCurve switch documentation, including Release Notes covering recently added features, visit the ProCurve Networking Web Site at **www.procurve.com**, click on **Technical support**, and then click on **Product Manuals (all)**.

- **Software Release Notes**—Release notes are posted on the ProCurve Networking web site and provide information on new software updates:
 - new features and how to configure and use them
 - software management, including downloading software to the switch
 - software fixes addressed in current and previous releases

To view and download a copy of the latest software release notes for your switch, refer to “Getting Documentation From the Web” on page 1-7.

- **Product Notes and Software Update Information**—The printed *Read Me First* shipped with your switch provides software update information, product notes, and other information. For the latest version, refer to “Getting Documentation From the Web” on page 1-7.
- **Installation and Getting Started Guide**—Use the *Installation and Getting Started Guide* shipped with your switch to prepare for and perform the physical installation. This guide also steps you through connecting the switch to your network and assigning IP addressing, as well as describing the LED indications for correct operation and trouble analysis. You can download a copy from the ProCurve Networking web site. (See “Getting Documentation From the Web” on page 1-7.)

- *Management and Configuration Guide*—Use this guide for information on topics such as:
 - various interfaces available on the switch
 - memory and configuration operation
 - interface access
 - IP addressing
 - time protocols
 - port configuration, trunking, and traffic control
 - SNMP, LLDP, and other network management topics
 - file transfers, switch monitoring, troubleshooting, and MAC address management
- *Advanced Traffic Management Guide*—Use this guide for information on topics such as:
 - VLANs: Static port-based and protocol VLANs, and dynamic GVRP VLANs
 - Spanning-Tree: 802.1s (MSTP)
 - Quality-of-Service (QoS)
- *Multicast and Routing Guide*—Use this guide for information topics such as:
 - IGMP
 - IP routing
- *Access Security Guide*—Use this guide for information on topics such as:
 - Local username and password security
 - Web-Based and MAC-based authentication
 - RADIUS and TACACS+ authentication
 - SSH (Secure Shell) and SSL (Secure Socket Layer) operation
 - 802.1X access control
 - Port security operation with MAC-based control
 - Authorized IP Manager security
 - Key Management System (KMS)

Getting Documentation From the Web

1. Go to the ProCurve Networking Web Site at
www.procurve.com
2. Click on **Technical support**.
3. Click on **Product manuals**.
4. Click on the product for which you want to view or download a manual.

Online Help

If you need information on specific parameters in the menu interface, refer to the online help provided in the interface. For example:

If you need information on a specific command in the CLI, type the command name followed by "help". For example:

```
ProCurve# write help
Usage: write <memory|terminal>

Description: View or save the running configuration of the switch.

        write terminal - displays the running configuration of the
                        switch on the terminal
        write memory   - saves the running configuration of the
                        switch to flash. The saved configuration
                        becomes the boot-up configuration of the switch
                        the next time it is booted.
```

If you need information on specific features in the ProCurve Web Browser Interface (hereafter referred to as the “web browser interface”), use the online help available for the web browser interface. For more information on web browser Help options, refer to “Online Help for the ProCurve Web Browser Interface” in the Management and Configuration Guide.

If you need further information on ProCurve switch technology, visit the ProCurve Networking web site at:

www.procurve.com

Need Only a Quick Start?

IP Addressing

If you just want to give the switch an IP address so that it can communicate on your network, or if you are not using VLANs, ProCurve recommends that you use the Switch Setup screen to quickly configure IP addressing. To do so, do one of the following:

- Enter **setup** at the CLI Manager level prompt.
Procurve# setup
- In the Main Menu of the Menu interface, select

8. Run Setup

For more on using the Switch Setup screen, see the *Installation and Getting Started Guide* you received with the switch.

To Set Up and Install the Switch in Your Network

Physical Installation

Use the ProCurve *Installation and Getting Started Guide* (shipped with the switch) for the following:

- Notes, cautions, and warnings related to installing and using the switch and its related modules
- Instructions for physically installing the switch in your network
- Quickly assigning an IP address and subnet mask, set a Manager password, and (optionally) configure other basic features.
- Interpreting LED behavior.

For the latest version of the *Installation and Getting Started Guide* for your switch, refer to “Getting Documentation From the Web” on page 1-7.

Overview

This chapter describes how to configure and use static, port-based and protocol-based VLANs on the switches covered in this guide.

For general information on how to use the switch's built-in interfaces, refer to these chapters in the *Management and Configuration Guide* for your switch:

- Chapter 3, "Using the Menu Interface"
- Chapter 4, "Using the Command Line Interface (CLI)"
- Chapter 5, "Using the Web Browser Interface"
- Chapter 6, "Switch Memory and Configuration"

Introduction

VLAN Features

Feature	Default	Menu	CLI	Web
view existing VLANs	n/a	page 2-23 thru 2-28	page 2-29	page 2-40
configuring static VLANs	default VLAN with VID = 1	page 2-23 thru 2-28	page 2-28	page 2-40

VLANs enable you to group users by logical function instead of physical location. This helps to control bandwidth usage within your network by allowing you to group high-bandwidth users on low-traffic segments and to organize users from different LAN segments according to their need for common resources and/or their use of individual protocols. You can also improve traffic control at the edge of your network by separating traffic of different protocol types. VLANs can also enhance your network security by creating separate subnets to help control in-band access to specific network resources.

General VLAN Operation

A VLAN is comprised of multiple ports operating as members of the same subnet (broadcast domain). Ports on multiple devices can belong to the same VLAN, and traffic moving between ports in the same VLAN is bridged (or “switched”). (Traffic moving between different VLANs must be routed.) A *static* VLAN is an 802.1Q-compliant VLAN configured with one or more ports that remain members regardless of traffic usage. (A *dynamic* VLAN is an 802.1Q-compliant VLAN membership that the switch temporarily creates on a port to provide a link to another port in the same VLAN on another device.)

This chapter describes *static* VLANs configured for port-based or protocol-based operation. Static VLANs are configured with a name, VLAN ID number (VID), and port members. (For *dynamic* VLANs, refer to chapter 3, “GVRP”.)

By default, the switches covered in this guide are 802.1Q VLAN-enabled and allow up to 2048 static and dynamic VLANs. (The default static VLAN setting is 8). 802.1Q compatibility enables you to assign each switch port to multiple VLANs, if needed.

Types of Static VLANs Available in the Switch

Port-Based VLANs

This type of static VLAN creates a specific layer-2 broadcast domain comprised of member ports that bridge IPv4 traffic among themselves. Port-Based VLAN traffic is routable on the switches covered in this guide.

Protocol-Based VLANs

This type of static VLAN creates a layer-3 broadcast domain for traffic of a particular protocol, and is comprised of member ports that bridge traffic of the specified protocol type among themselves. Some protocol types are routable on the switches covered in this guide. Refer to table 2-1 on page 2-7.

Designated VLANs

The switch uses these static, port-based VLAN types to separate switch management traffic from other network traffic. While these VLANs are not limited to management traffic only, they can provide improved security and availability for management traffic.

- **The Default VLAN:** This port-based VLAN is always present in the switch and, in the default configuration, includes all ports as members (page 2-46).
- **The Primary VLAN:** The switch uses this port-based VLAN to run certain features and management functions, including DHCP/Bootp responses for switch management. In the default configuration, the Default VLAN is also the Primary VLAN. However, you can designate another, port-based, non-default VLAN, as the Primary VLAN (page 2-46).
- **The Secure Management VLAN:** This optional, port-based VLAN establishes an isolated network for managing the ProCurve switches that support this feature. Access to this VLAN and to the switch's management functions are available only through ports configured as members (page 2-47).
- **Voice VLANs:** This optional, port-based VLAN type enables you to separate, prioritize, and authenticate voice traffic moving through your network, and to avoid the possibility of broadcast storms affecting VoIP (Voice-over-IP) operation (page 2-55).

Note

In a multiple-VLAN environment that includes some older switch models there may be problems related to the same MAC address appearing on different ports and VLANs on the same switch. In such cases the solution is to impose some cabling and VLAN restrictions. For more on this topic, refer to “Multiple VLAN Considerations” on page 2-18.

Terminology

Dynamic VLAN: An 802.1Q VLAN membership temporarily created on a port linked to another device, where both devices are running GVRP. (See also **Static VLAN**.) For more information, refer to chapter 3, “GVRP” .

Static VLAN: A port-based or protocol-based VLAN configured in switch memory. (See also **Dynamic VLAN**.)

Tagged Packet: A packet that carries an IEEE 802.1Q VLAN ID (VID), which is a two-byte extension that precedes the source MAC address field of an ethernet frame. A VLAN tag is layer 2 data and is transparent to higher layers.

Tagged VLAN: A VLAN that complies with the 802.1Q standard, including priority settings, and allows a port to join multiple VLANs. (See also **Untagged VLAN**.)

Untagged Packet: A packet that does not carry an IEEE 802.1Q VLAN ID (VID).

Untagged VLAN: A VLAN that does not use or forward 802.1Q VLAN tagging, including priority settings. A port can be a member of only one untagged VLAN of a given type (port-based and the various protocol-based types). (See also **Tagged VLAN**.)

VID: The acronym for a VLAN Identification Number. Each 802.1Q-compliant VLAN must have its own unique VID number, and that VLAN must be given the same VID in every device in which it is configured.

Static VLAN Operation

A group of networked ports assigned to a VLAN form a broadcast domain that is separate from other VLANs that may be configured on the switch. On a given switch, packets are bridged between source and destination ports that belong to the same VLAN. Thus, all ports passing traffic for a particular subnet address should be configured to the same VLAN. Cross-domain broadcast traffic in the switch is eliminated and bandwidth is saved by not allowing packets to flood out all ports.

Table 2-1. Comparative Operation of Port-Based and Protocol-Based VLANs

	Port-Based VLANs	Protocol-Based VLANs
IP Addressing	Usually configured with at least one unique IP address. You can create a port-based VLAN without an IP address. However, this limits the switch features available to ports on that VLAN. (Refer to “How IP Addressing Affects Switch Operation” in the chapter “Configuring IP Addressing” in the <i>Management and Configuration Guide</i> for the switch.) You can also use multiple IP addresses to create multiple subnets within the same VLAN. (For more on this topic, refer to the chapter on “Configuring IP Addressing” in the <i>Management and Configuration Guide</i> for the switch.)	You can configure IP addresses on all protocol VLANs. However, IP addressing is used only on IPv4 and IPv6 protocol VLANs. Restrictions: When you configure an IP address on a VLAN interface, the following restrictions apply: Loopback interfaces share the same IP address space with VLAN configurations. The maximum number of IP addresses supported on a switch is 2048, which includes all IP addresses configured for both VLANs and loopback interfaces (except for the default loopback IP address 127.0.0.1). Each IP address that you configure on a VLAN interface must be unique in the switch. This means that the address cannot be used by a VLAN interface or another loopback interface. For more information, refer to the chapter on “Configuring IP Addressing” in the <i>Management and Configuration Guide</i>.

	Port-Based VLANs	Protocol-Based VLANs
Untagged VLAN Membership	A port can be a member of one untagged, port-based VLAN. All other port-based VLAN assignments for that port must be tagged.	A port can be an untagged member of one protocol VLAN of a specific protocol type (such as IPX or IPv6). If the same protocol type is configured in multiple protocol VLANs, then a port can be an untagged member of only one of those protocol VLANs. For example, if you have two protocol VLANs, 100 and 200, and both include IPX, then a port can be an untagged member of either VLAN 100 or VLAN 200, but not both VLANs. A port's untagged VLAN memberships can include up to four different protocol types. This means that a port can be an untagged member of one of the following: • Four single-protocol VLANs • Two protocol VLANs where one VLAN includes a single protocol and the other includes up to three protocols • One protocol VLAN where the VLAN includes four protocols
Tagged VLAN Membership	A port can be a tagged member of any port-based VLAN. See above.	A port can be a tagged member of any protocol-based VLAN. See above.
Routing	The switch can internally route IP (IPv4) traffic between port-based VLANs and between port-based and IPv4 protocol-based VLANs if the switch configuration enables IP routing. If the switch is not configured to route traffic internally between port-based VLANs, then an external router must be used to move traffic between VLANs.	If the switch configuration enables IP routing, the switch can internally route IPv4 traffic as follows: • Between multiple IPv4 protocol-based VLANs • Between IPv4 protocol-based VLANs and port-based VLANs. Other protocol-based VLANs require an external router for moving traffic between VLANs. Note: NETbeui and SNA are non-routable protocols. End stations intended to receive traffic in these protocols must be attached to the same physical network.
Commands for Configuring Static VLANs	vlan < VID > [tagged untagged < [e] port-list >]	vlan < VID > protocol < ipx ipv4 ipv6 arp appletalk sna netbeui > vlan < VID > [tagged untagged < [e] port-list >]

VLAN Environments

You can configure different VLAN types in any combination. Note that the default VLAN will always be present. (For more on the default VLAN, refer to “VLAN Support and the Default VLAN” on page 2-46.)

Table 2-2. VLAN Environments

VLAN Environment	Elements
The default VLAN (port-based; VID of "1") Only	In the default VLAN configuration, all ports belong to VLAN 1 as untagged members. VLAN 1 is a port-based VLAN, for IPv4 traffic.
Multiple VLAN Environment	In addition to the default VLAN, the configuration can include one or more other port-based VLANs and one or more protocol VLANs. (The switches covered in this guide allow up to 2048 (vids up to 4094) VLANs of all types.) Using VLAN tagging, ports can belong to multiple VLANs of all types. Enabling routing on the switch enables the switch to route IPv4 traffic between port-based VLANs and between port-based VLANs and IPv4 protocol VLANs. Routing other types of traffic between VLANs requires an external router capable of processing the appropriate protocol(s).

VLAN Operation

The Default VLAN. In figure 2-1, all ports belong to the default VLAN, and devices connected to these ports are in the same broadcast domain. Except for an IP address and subnet, no configuration steps are needed.

Figure 2-1. Example of a Switch in the Default VLAN Configuration

Multiple Port-Based VLANs. In figure 2-2, routing within the switch is disabled (the default). This means that communication between any routable VLANs on the switch must go through the external router. In this case, VLANs "W" and "X" can exchange traffic through the external router, but traffic in VLANs "Y" and "Z" is restricted to the respective VLANs. Note that VLAN 1, the default VLAN, is also present, but not shown. (The default VLAN cannot be deleted from the switch. However, ports assigned to other VLANs can be removed from the default VLAN, if desired.) If internal (IP) routing is enabled on the switch, then the external router is not needed for traffic to move

between port-based VLANs.

Figure 2-2. Example of Multiple VLANs on the Switch

Protocol VLAN Environment. Figure 2-2 can also be applied to a protocol VLAN environment. In this case, VLANs “W” and “X” represent routable protocol VLANs. VLANs “Y” and “Z” can be any protocol VLAN. As noted for the discussion of multiple port-based VLANs, VLAN 1 is not shown. Enabling internal (IP) routing on the switch allows IP traffic to move between VLANs on the switch. However, routable, non-IP traffic always requires an external router.

Routing Options for VLANs

Table 2-3. Options for Routing Between VLAN Types in the Switch

	Port-Based	IPX	IPv4	IPv6	ARP	Apple -Talk	SNA ²	Netbeui ²
Port-Based	Yes	—	Yes	—	—	—	—	—
Protocol								
IPX	—	Yes ¹	—	—	—	—	—	—
IPv4	Yes	—	Yes	—	—	—	—	—
IPv6	—	—	—	Yes ¹	—	—	—	—
ARP	—	—	—	—	Yes ¹	—	—	—
AppleTalk	—	—	—	—	—	Yes ¹	—	—

	Port- Based	IPX	IPv4	IPv6	ARP	Apple -Talk	SNA ²	Netbeui ²
SNA ²	—	—	—	—	—	—	—	—
NETbeui ²	—	—	—	—	—	—	—	—

¹Requires an external router to route between VLANs.

²Not a routable protocol type. End stations intended to receive traffic in these protocols must be attached to the same physical network.

Overlapping (Tagged) VLANs

A port can be a member of more than one VLAN of the same type if the device to which the port connects complies with the 802.1Q VLAN standard. For example, a port connected to a central server using a network interface card (NIC) that complies with the 802.1Q standard can be a member of multiple VLANs, allowing members of multiple VLANs to use the server. Although these VLANs cannot communicate with each other through the server, they can all access the server over the same connection from the switch. Where VLANs overlap in this way, VLAN “tags” are used in the individual packets to distinguish between traffic from different VLANs. A VLAN tag includes the particular VLAN I.D. (VID) of the VLAN on which the packet was generated.

Figure 2-3. Example of Overlapping VLANs Using the Same Server

Similarly, using 802.1Q-compliant switches, you can connect multiple VLANs through a single switch-to-switch link.

Figure 2-4. Example of Connecting Multiple VLANs Through the Same Link

Introducing Tagged VLAN Technology into Networks Running Legacy (Untagged) VLANs. You can introduce 802.1Q-compliant devices into networks that have built untagged VLANs based on earlier VLAN technology. The fundamental rule is that legacy/untagged VLANs require a separate link for each VLAN, while 802.1Q, or tagged VLANs can combine several VLANs in one link. This means that on the 802.1Q-compliant device, separate ports (configured as untagged) must be used to connect separate VLANs to non-802.1Q devices.

Figure 2-5. Example of Tagged and Untagged VLAN Technology in the Same Network

For more information on VLANs, refer to:

- “Overview of Using VLANs” (page 2-46)
- “Menu: Configuring VLAN Parameters (page 2-22)

- “CLI: Configuring VLAN Parameters” (page 2-22)
- “Web: Viewing and Configuring VLAN Parameters” (page 2-40)
- “VLAN Tagging Information” (page 2-41)
- “Effect of VLANs on Other Switch Features” (page 2-57)
- “VLAN Restrictions” (page 2-59)

Per-Port Static VLAN Configuration Options

The following figure and table show the options you can use to assign individual ports to a static VLAN. Note that GVRP, if configured, affects these options and VLAN behavior on the switch. The display below shows the per-port VLAN configuration options. Table 2-4 briefly describes these options.

Figure 2-6. Comparing Per-Port VLAN Options With and Without GVRP

Table 2-4. Per-Port VLAN Configuration Options

Parameter	Effect on Port Participation in Designated VLAN
Tagged	Allows the port to join multiple VLANs.
Untagged	Allows VLAN connection to a device that is configured for an untagged VLAN instead of a tagged VLAN. A port can be an untagged member of only one port-based VLAN. A port can also be an untagged member of only one protocol-based VLAN for any given protocol type. For example, if the switch is configured with the default VLAN plus three protocol-based VLANs that include IPX, then port 1 can be an untagged member of the default VLAN and one of the protocol-based VLANs.

Parameter	Effect on Port Participation in Designated VLAN
No - or - Auto	No: Appears when the switch is not GVRP-enabled; prevents the port from joining that VLAN. Auto: Appears when GVRP is enabled on the switch; allows the port to dynamically join any advertised VLAN that has the same VID
Forbid	Prevents the port from joining the VLAN, even if GVRP is enabled on the switch.

VLAN Operating Rules

- **DHCP/Bootp:** If you are using DHCP/Bootp to acquire the switch's configuration, packet time-to-live, and TimeP information, you must designate the VLAN on which DHCP is configured for this purpose as the Primary VLAN. (In the factory-default configuration, the DEFAULT_VLAN is the Primary VLAN.)
- **Per-VLAN Features:** IGMP and some other features operate on a “per VLAN” basis. This means you must configure such features separately for each VLAN in which you want them to operate.
- **Default VLAN:** You can rename the default VLAN, but you cannot change its VID (1) or delete it from the switch.
- **VLAN Port Assignments:** Any ports *not* specifically removed from the default VLAN remain in the DEFAULT_VLAN, regardless of other port assignments. Also, a port must always be a tagged or untagged member of at least one port-based VLAN.
- **Voice-Over-IP (VoIP):** VoIP operates only over static, port-based VLANs.
- **Multiple VLAN Types Configured on the Same Port:** A port can simultaneously belong to both port-based and protocol-based VLANs.
- **Protocol Capacity:** A protocol-based VLAN can include up to four protocol types. In protocol VLANs using the IPv4 protocol, ARP must be one of these protocol types (to support normal IP network operation). Otherwise, IP traffic on the VLAN is disabled. If you configure an IPv4

protocol VLAN that does not already include the ARP VLAN protocol, the switch displays this message:

```
ProCurve(config)# vlan 97 protocol ipv4  
Caution: IPv4 assigned without ARP  
undeliverable IP packets.
```

Indicates a protocol VLAN configured
with IPv4, but not ARP.

- **Deleting Static VLANs:** On the switches covered in this guide you can delete a VLAN regardless of whether there are currently any ports belonging to that VLAN. (The ports are moved to the default VLAN.)
- **Adding or Deleting VLANs:** Changing the number of VLANs supported on the switch requires a reboot. (From the CLI, you must perform a **write memory** command before rebooting.) Other VLAN configuration changes are dynamic.
- **Inbound Tagged Packets:** If a tagged packet arrives on a port that is not a tagged member of the VLAN indicated by the packet's VID, the switch drops the packet. Similarly, the switch will drop an inbound, tagged packet if the receiving port is an *untagged* member of the VLAN indicated by the packet's VID.
- **Untagged Packet Forwarding:** To enable an inbound port to forward an untagged packet, the port must be an untagged member of either a protocol VLAN matching the packet's protocol or an untagged member of a port-based VLAN. That is, when a port receives an incoming, untagged packet, it processes the packet according to the following ordered criteria:
 - a. If the port has no untagged VLAN memberships, the switch drops the packet.
 - b. If the port has an untagged VLAN membership in a protocol VLAN that matches the protocol type of the incoming packet, then the switch forwards the packet on that VLAN.
 - c. If the port is a member of an untagged, port-based VLAN, the switch forwards the packet to that VLAN. Otherwise, the switch drops the packet.

Figure 2-7. Untagged VLAN Operation

- **Tagged Packet Forwarding:** If a port is a tagged member of the same VLAN as an inbound, tagged packet received on that port, then the switch forwards the packet to an outbound port on that VLAN. (To enable the forwarding of tagged packets, any VLAN to which the port belongs as a

tagged member must have the same VID as that carried by the inbound, tagged packets generated on that VLAN.)

Figure 2-8. Tagged VLAN Operation

See also "Multiple VLAN Considerations" on page 2-18.

General Steps for Using VLANs

1. Plan your VLAN strategy and create a map of the logical topology that will result from configuring VLANs. Include consideration for the interaction between VLANs and other features such as Spanning Tree Protocol, port trunking, and IGMP. (Refer to "Effect of VLANs on Other Switch Features" on page 2-57.) If you plan on using dynamic VLANs, include the port configuration planning necessary to support this feature. (Refer to chapter 3, "GVRP".)

By default, VLAN support is enabled and the switch is configured for eight VLANs.

2. Configure at least one VLAN in addition to the default VLAN.
3. Assign the desired switch ports to the new VLAN(s).

4. If you are managing VLANs with SNMP in an IP network, the VLAN through which you are managing the switch must have an IP address. For information on the procedure and restrictions when you configure an IP address on a VLAN interface, refer to Table 2-1 on page 2-7.

Multiple VLAN Considerations

Switches use a *forwarding database* to maintain awareness of which external devices are located on which VLANs. Some switches, such as the switches covered in this guide, have a *multiple forwarding database*, which means the switch allows multiple database entries of the same MAC address, with each entry showing the (different) source VLAN and source port. Other switch models have a *single forwarding database*, which means they allow only one database entry of a unique MAC address, along with the source VLAN and source port on which it is found. All VLANs on a switch use the same MAC address. Thus, connecting a multiple forwarding database switch to a single forwarding database switch where multiple VLANs exist imposes some cabling and port VLAN assignment restrictions. Table 2-5 illustrates the functional difference between the two database types.

Table 2-5. Example of Forwarding Database Content

Multiple Forwarding Database			Single Forwarding Database		
MAC Address	Destination VLAN ID	Destination Port	MAC Address	Destination VLAN ID	Destination Port
0004ea-84d9f4	1	A5	0004ea-84d9f4	100	A9
0004ea-84d9f4	22	A12	0060b0-880af9	105	A10
0004ea-84d9f4	44	A20	0060b0-880a81	107	A17
0060b0-880a81	33	A20			
This database allows multiple destinations for the same MAC address. If the switch detects a new destination for an existing MAC entry, it just adds a new instance of that MAC to the table.			This database allows only one destination for a MAC address. If the switch detects a new destination for an existing MAC entry, it replaces the existing MAC instance with a new instance showing the new destination.		

Table 2-6 lists the database structure of current ProCurve switch models.

Table 2-6. Forwarding Database Structure for Managed ProCurve Switches

Multiple Forwarding Databases*	Single Forwarding Database*
Switch 8212zl	Switch 1600M/2400M/2424M
Series 6400cl switches	Switch 4000M/8000M
Switch 6200yl	Series 2500 switches
Switch 6108	Switch 2000
Series 5400zl switches	Switch 800T
Series 5300xl switches	
Series 4200vl switches	
Series 4100gl switches	
Series 3500yl switches	
Series 3400cl switches	
Switch 2900	
Switch 2810

Series 2600/2600-PWR switches	
Series 2510 switches	
*To determine whether other vendors' devices use single-forwarding or multiple-forwarding database architectures, refer to the documentation provided for those devices.	

Single Forwarding Database Operation

When a packet arrives with a destination MAC address that matches a MAC address in the switch's forwarding table, the switch tries to send the packet to the port listed for that MAC address. But, if the destination port is in a different VLAN than the VLAN on which the packet was received, the switch drops the packet. This is not a problem for a switch with a multiple forwarding database (refer to table 2-6, above) because the switch allows multiple instances of a given MAC address; one for each valid destination. However, a switch with a single forwarding database allows only one instance of a given MAC address. If (1) you connect the two types of switches through multiple ports or trunks belonging to different VLANs, and (2) enable routing on the switch having the multiple forwarding database; then, on the switch having the single forwarding database, the port and VLAN record it maintains for the connected multiple-forwarding-database switch can frequently change. This causes poor performance and the appearance of an intermittent or broken connection.

Example of an Unsupported Configuration and How To Correct It

The Problem. In figure 2-9, the MAC address table for Switch 8000M will sometimes record the switch as accessed on port A1 (VLAN 1), and other times as accessed on port B1 (VLAN 2):

Figure 2-9. Example of Invalid Configuration for Single-Forwarding to Multiple-Forwarding Database Devices in a Multiple VLAN Environment

In figure 2-9, PC "A" sends an IP packet to PC "B".

1. The packet enters VLAN 1 in the Switch 8000 with the 2900 switch's MAC address in the destination field. Because the 8000M has not yet learned this MAC address, it does not find the address in its address table, and floods the packet out all ports, including the VLAN 1 link (port "A1") to the 2900 switch. The 2900 switch then routes the packet through the VLAN 2 link to the 8000M, which forwards the packet on to PC "B". Because the 8000M received the packet from the 2900 switch on VLAN 2 (port "B1"), the 8000M's single forwarding database records the 2900 switch as being on port "B1" (VLAN 2).
2. PC "A" now sends a second packet to PC "B". The packet again enters VLAN 1 in the Switch 8000 with the 2900 switch's MAC address in the destination field. However, this time the Switch 8000M's single forwarding database indicates that the 2900 is on port B1 (VLAN 2), and the 8000M drops the packet instead of forwarding it.
3. Later, the 2900 switch transmits a packet to the 8000M through the VLAN 1 link, and the 8000M updates its address table to indicate that the 2900 switch is on port A1 (VLAN 1) instead of port B1 (VLAN 2). Thus, the 8000M's information on the location of the 2900 switch changes over

time. For this reason, the 8000M discards some packets directed through it for the 2900 switch, resulting in poor performance and the appearance of an intermittent or broken link.

The Solution. To avoid the preceding problem, use only one cable or port trunk between the single-forwarding and multiple-forwarding database devices, and configure the link with multiple, tagged VLANs.

Figure 2-10. Example of a Solution for Single-Forwarding to Multiple-Forwarding Database Devices in a Multiple VLAN Environment

Now, the 8000M forwarding database always lists the 2900 MAC address on port A1, and the 8000M will send traffic to either VLAN on the 2900.

To increase the network bandwidth of the connection between the devices, you can use a trunk of multiple physical links rather than a single physical link.

Multiple Forwarding Database Operation

If you want to connect one of the switches covered by this guide to another switch that has a multiple forwarding database, you can use either or both of the following connection options:

- A separate port or port trunk interface for each VLAN. This results in a forwarding database having multiple instances of the same MAC address with different VLAN IDs and port numbers. (See table 2-5.) The fact that the switches covered by this guide use the same MAC address on all VLAN interfaces causes no problems.
- The same port or port trunk interface for multiple (tagged) VLANs. This results in a forwarding database having multiple instances of the same MAC address with different VLAN IDs, but the same port number.

Allowing multiple entries of the same MAC address on different VLANs enables topologies such as the following:

Figure 2-11. Example of a Valid Topology for Devices Having Multiple Forwarding Databases in a Multiple VLAN Environment

Configuring VLANs

Menu: Configuring Port-Based VLAN Parameters

The Menu interface enables you to configure and view port-based VLANs.

Note

The Menu interface configures and displays only port-based VLANs. The CLI configures and displays port-based *and* protocol-based VLANs (page 2-28).

In the factory default state, support is enabled for up to 256 VLANs. (You can reconfigure the switch to support up to 2048 (vids up to 4094) VLANs.) Also, in the default configuration, all ports on the switch belong to the default VLAN and are in the same broadcast/multicast domain. (The default VLAN is also the default Primary VLAN—refer to “The Primary VLAN” on page 2-46.) In addition to the default VLAN, you can configure additional static VLANs by adding new VLAN names and VIDs, and then assigning one or more ports to each VLAN. (The maximum of 2048 VLANs includes the default VLAN, all additional static VLANs you configure, and any dynamic VLANs the switch creates if you enable GVRP—page 3-1.) Note that each port can be assigned to multiple VLANs by using VLAN tagging. (See “802.1Q VLAN Tagging” on page 2-41.)

To Change VLAN Support Settings

This section describes:

- Changing the maximum number of VLANs to support
- Changing the Primary VLAN selection (See “Changing the Primary VLAN” on page 2-35.)
- Enabling or disabling dynamic VLANs (Refer to chapter 3, “GVRP” .)

1. From the Main Menu select:

2. Switch Configuration

8. VLAN Menu ...

1. VLAN Support

You will then see the following screen:

Figure 2-12. The Default VLAN Support Screen

2. Press **[E]** (for **E**dit), then do one or more of the following:
- To change the maximum number of VLANs, type the new number (1 - 2048 allowed; default 256).
 - To designate a different VLAN as the Primary VLAN, select the **Primary VLAN** field and use the space bar to select from the existing options. (Note that the Primary VLAN must be a static, port-based VLAN.)
 - To enable or disable dynamic VLANs, select the **GVRP Enabled** field and use the Space bar to toggle between options. (For GVRP information, refer to chapter 3, “GVRP” .)

Note

For optimal switch memory utilization, set the number of VLANs at the number you will likely be using or a few more. If you need more VLANs later, you can increase this number, but a switch reboot will be required at that time.

3. Press **[Enter]** and then **[S]** to save the VLAN support configuration and return to the VLAN Menu screen.
-

If you changed the value for **Maximum VLANs to support**, you will see an asterisk next to the **VLAN Support** option (see below).

Figure 2-13. VLAN Menu Screen Indicating the Need To Reboot the Switch

- If you changed the VLAN Support option, you must reboot the switch before the Maximum VLANs change can take effect. You can go on to configure other VLAN parameters first, but remember to reboot the switch when you are finished.
- If you did not change the VLAN Support option, a reboot is not necessary.

4. Press **[0]** to return to the Main Menu.

Adding or Editing VLAN Names

Use this procedure to add a new VLAN or to edit the name of an existing VLAN.

1. From the Main Menu select:

2. Switch Configuration

8. VLAN Menu ...

2. VLAN Names

If multiple VLANs are not yet configured you will see a screen similar to figure 2-14:

Figure 2-14. The Default VLAN Names Screen

2. Press **[A]** (for **Add**). You will then be prompted for a new VLAN name and VLAN ID:

```
802.1Q VLAN ID : 1
Name : _
```

3. Type in a VID (VLAN ID number). This can be any number from 2 to 4094 that is not already being used by another VLAN. (The switch reserves “1” for the default VLAN.)

Remember that a VLAN *must* have the same VID in every switch in which you configure that same VLAN. (GVRP dynamically extends VLANs with correct VID numbering to other switches. Refer to chapter 3, “GVRP” .)

4. Press **[↓]** to move the cursor to the **Name** line and type the VLAN name (up to 12 characters, with no spaces) of a new VLAN that you want to add, then press **[Enter]**.
(Avoid these characters in VLAN names: @, #, \$, ^, &, *, (, and).)
5. Press **[S]** (for **Save**). You will then see the VLAN Names screen with the new VLAN listed.

Figure 2-15. Example of VLAN Names Screen with a New VLAN Added

6. Repeat steps 2 through 5 to add more VLANs.

Remember that you can add VLANs until you reach the number specified in the **Maximum VLANs to support** field on the VLAN Support screen (see figure 2-12 on page 2-23). This includes any VLANs added dynamically due to GVRP operation.

7. Return to the VLAN Menu to assign ports to the new VLAN(s) as described in the next section, “Adding or Changing a VLAN Port Assignment”.

Adding or Changing a VLAN Port Assignment

Use this procedure to add ports to a VLAN or to change the VLAN assignment(s) for any port. (Ports not specifically assigned to a VLAN are automatically in the default VLAN.)

1. From the Main Menu select:

2. Switch Configuration

8. VLAN Menu ...

3. VLAN Port Assignment

You will then see a VLAN Port Assignment screen similar to the following:

Note

The “VLAN Port Assignment” screen displays up to 32 static, port-based VLANs in ascending order, by VID. If the switch configuration includes more than 32 such VLANs, use the CLI **show vlans [VID | ports < port-list >]** command to list data on VLANs having VIDs numbered sequentially higher than the first 32.

Default: In this example, the “VLAN-22” has been defined, but no ports have yet been assigned to it. (“No” means the port is not assigned to that VLAN.)

Using GVRP? If you plan on using GVRP, any ports you don’t want to join should be changed to “Forbid”.

A port can be assigned to several VLANs, but only one of those assignments can be “Untagged”.

===== CONSOLE - MANAGER MODE =====
Switch Configuration - VLAN - VLAN Port Assignment

Port	DEFAULT_VLAN	VLAN-22	Port	DEFAULT_VLAN	VLAN-22
A1	Untagged	No	A8	Untagged	No
A2	Tagged	No	A9	Untagged	No
A3	Untagged	No	A10	Untagged	No
A4	Untagged	No	A11	Untagged	No
A5	Untagged	No	A12	Untagged	No
A6	Untagged	No	A13	Untagged	No
A7	Untagged	No	A14	Untagged	No

Actions-> **Cancel** Edit Save Help

Cancel changes and return to previous screen.
Use arrow keys to change action selection and <Enter> to execute action.

Figure 2-16. Example of the Port-Based VLAN Port Assignment Screen in the Menu Interface

- To change a port’s VLAN assignment(s):
 - Press **[E]** (for **Edit**).
 - Use the arrow keys to select a VLAN assignment you want to change.
 - Press the Space bar to make your assignment selection (**No**, **Tagged**, **Untagged**, or **Forbid**).

Note

For GVRP Operation: If you enable GVRP on the switch, “No” converts to “Auto”, which allows the VLAN to dynamically join an advertised VLAN that has the same VID. See “Per-Port Options for Dynamic VLAN Advertising and Joining” on page 3-9.

Untagged VLANs: Only one untagged VLAN is allowed per port. Also, there must be at least one VLAN assigned to each port. In the factory default configuration, all ports are assigned to the default VLAN (DEFAULT_VLAN).

For example, if you want ports A4 and A5 to belong to both DEFAULT_VLAN and VLAN-22, and ports A6 and A7 to belong only to VLAN-22, you would use the settings in figure page 2-28. (This example assumes the default GVRP setting—disabled—and that you do not plan to enable GVRP later.)

Ports A4 and A5 are assigned to both VLANs.

Ports A6 and A7 are assigned only to VLAN-22.

All other ports are assigned only to the Default VLAN.

```

-----  CONSOLE - MANAGER MODE  -----
                Switch Configuration - VLAN - VLAN Port Assignment

Port  DEFAULT_VLAN  VLAN-22  |  Port  DEFAULT_VLAN  VLAN-22
-----+-----
A1 | Untagged  No    |  A8 | Untagged  No
A2 | Untagged  No    |  A9 | Untagged  No
A3 | Untagged  No    |  A10 | Untagged  No
A4 | Untagged  Tagged |  A11 | Untagged  No
A5 | Untagged  Tagged |  A12 | Untagged  No
A6 | No        Untagged |  A13 | Untagged  No
A7 | No        Untagged |  A14 | Untagged  No

Actions->  C a n c e l      E d i t      S a v e      H e l p

Select the tagging mode for the port/VLAN combination.
Use arrow keys to change field selection, <Space> to toggle field choices,
and <Enter> to go to Actions.

```

Figure 2-17. Example of Port-Based VLAN Assignments for Specific Ports

For information on VLAN tags (“Untagged” and “Tagged”), refer to “802.1Q VLAN Tagging” on page 2-41.

- d. If you are finished assigning ports to VLANs, press **[Enter]** and then **[S]** (for **Save**) to activate the changes you've made and to return to the Configuration menu. (The console then returns to the VLAN menu.)
3. Return to the Main menu.

CLI: Configuring Port-Based and Protocol-Based VLAN Parameters

In the factory default state, all ports on the switch belong to the (port-based) default VLAN (DEFAULT_VLAN; VID = 1) and are in the same broadcast/multicast domain. (The default VLAN is also the Primary VLAN. For more on this topic, refer to “The Primary VLAN” on page 2-46.) You can configure up to 255 additional static VLANs by adding new VLAN names, and then assigning one or more ports to each VLAN. (The switch accepts a maximum of 2048 (vids numbered up to 4094) VLANs, including the default VLAN and any dynamic VLANs the switch creates if you enable GVRP. Refer to chapter 3, “GVRP”.) Note that each port can be assigned to multiple VLANs by using VLAN tagging. (See “802.1Q VLAN Tagging” on page 2-41.)

VLAN Commands	Page
show vlans	below
show vlans < vid >	2-33
show vlans ports <port-list>	
max-vlans <1-2048>	2-34
primary-vlan < vid >	2-35
[no] vlan < vid >	2-36
auto < port-list >	2-38 (Available if GVRP enabled.)
forbid	2-38
name < vlan-name >	2-38
protocol < protocol-list >	2-36
tagged < port-list >	2-38
untagged < port-list >	2-38
voice	2-55
static-vlan < vlan-id >	2-38 (Available if GVRP enabled.)

Displaying the Switch’s VLAN Configuration. The **show vlans** command lists the VLANs currently running in the switch, with VID, VLAN name, and VLAN status. Dynamic VLANs appear only if the switch is running with GVRP enabled and one or more ports has dynamically joined an advertised VLAN. (In the default configuration, GVRP is disabled. (Refer to chapter 3, “GVRP” .)

Syntax: show vlans

Maximum VLANs to support: Shows the number of VLANs the switch can currently support. (Default: 256 Maximum: 2048)

Primary VLAN: Refer to “The Primary VLAN” on page 2-46.

Management VLAN: Refer to “The Secure Management VLAN” on page 2-47.

802.1Q VLAN ID: The VLAN identification number, or VID. Refer to “Terminology” on page 2-6.

Name: The default or specified name assigned to the VLAN. For a static VLAN, the default name consists of **VLAN-x** where “x” matches the VID assigned to that VLAN. For a dynamic VLAN, the name consists of **GVRP_x** where “x” matches the applicable VID.

Status:

Port-Based: *Port-Based, static VLAN*

Protocol: *Protocol-Based, static VLAN*

Dynamic: *Port-Based, temporary VLAN learned through GVRP (Refer to chapter 3, “GVRP” .)*

Voice: *Indicates whether a (port-based) VLAN is configured as a voice VLAN. Refer to “Voice VLANs” on page 2-55.*

Jumbo: *Indicates whether a VLAN is configured for Jumbo packets. For more on jumbos, refer to the chapter titled “Port Traffic Controls” in the Management and Configuration Guide for your switch.*

For example:

ProCurve # show vlans						
Status and Counters - VLAN Information						
Maximum VLANs to support : 8						
Primary VLAN : DEFAULT_VLAN						
Management VLAN :						
802.1Q	VLAN ID	Name	Status	Voice	Jumbo	
1		DEFAULT_VLAN	Port-based	No	No	
10		VLAN_10	Port-based	Yes	Yes	
15		VLAN_15	Port-based	No	No	
20		VLAN_20	Protocol	No	No	
33		GVRP_33	Dynamic	No	No	

When GVRP is disabled (the default), Dynamic VLANs do not exist on the switch and do not appear in this listing. (Refer to chapter 3, “GVRP” .)

Figure 2-18. Example of “Show VLAN” Listing (GVRP Enabled)

Displaying the VLAN Membership of One or More Ports.

This command shows to which VLAN a port belongs.

Syntax: show vlan ports < port-list > [detail]

Displays VLAN information for an individual port or a group of ports, either cumulatively or on a detailed per-port basis.

port-list: *Specify a single port number, a range of ports (for example, a1-a16), or all.*

detail: *Displays detailed VLAN membership information on a per-port basis.*

Descriptions of items displayed by the command are provided below.

Port name: *The user-specified port name, if one has been assigned.*

VLAN ID: *The VLAN identification number, or VID.*

Name: *The default or specified name assigned to the VLAN. For a static VLAN, the default name consists of **VLAN-x** where “x” matches the VID assigned to that VLAN. For a dynamic VLAN, the name consists of **GVRP_x** where “x” matches the applicable VID.*

Status:

Port-Based: *Port-Based, static VLAN*

Protocol: *Protocol-Based, static VLAN*

Dynamic: *Port-Based, temporary VLAN learned through GVRP.*

Voice: *Indicates whether a (port-based) VLAN is configured as a voice VLAN.*

Jumbo: *Indicates whether a VLAN is configured for Jumbo packets. For more on jumbos, refer to the chapter titled “Port Traffic Controls” in the Management and Configuration Guide for your switch.*

Mode: *Indicates whether a VLAN is tagged or untagged.*

Figure 2-19 is an example of the output when the **detail** option is not used.

ProCurve# show vlan ports a1-a33

Status and Counters - VLAN Information - for ports a1-a33

802.1Q	VLAN ID	Name	Status	Voice
1		DEFAULT_VLAN	Port-based	No
10		VLAN_10	Port-based	Yes
15		VLAN_15	Port-based	No
20		VLAN_20	Protocol	No
33		GVRP_33	Dynamic	No

Figure 2-19. Example of “Show VLAN Ports” Cumulative Listing

Figure 2-20 is an example of the output when the **detail** option is used.

```
ProCurve# show vlan ports a1-a4 detail
```

Status and Counters - VLAN Information - for ports A1

Port name: Voice_Port

VLAN ID	Name	Status	Voice	Jumbo	Mode
1	DEFAULT_VLAN	Port-based	No	No	Untagged
10	VLAN_10	Port-based	Yes	No	Tagged

Status and Counters - VLAN Information - for ports A2

Port name: Uplink_Port

VLAN ID	Name	Status	Voice	Jumbo	Mode
1	DEFAULT_VLAN	Port-based	No	No	Untagged
20	VLAN_20	Protocol	No	No	Tagged
33	GVRP_33	Dynamic	No	No	Tagged

Status and Counters - VLAN Information - for ports A3

VLAN ID	Name	Status	Voice	Jumbo	Mode
1	DEFAULT_VLAN	Port-based	No	No	Untagged

Status and Counters - VLAN Information - for ports A4

VLAN ID	Name	Status	Voice	Jumbo	Mode
1	DEFAULT_VLAN	Port-based	No	No	Untagged

Figure 2-20. Example of “Show VLAN Ports” Detail Listing

Displaying the Configuration for a Particular VLAN . This command uses the VID to identify and display the data for a specific static or dynamic VLAN.

Syntax: show vlans < vlan-id >

802.1Q VLAN ID: *The VLAN identification number, or VID. Refer to “Terminology” on page 2-6.*

Name: *The default or specified name assigned to the VLAN. For a static VLAN, the default name consists of **VLAN-x** where “x” matches the VID assigned to that VLAN. For a dynamic VLAN, the name consists of **GVRP_x** where “x” matches the applicable VID.*

Status:

Port-Based: *Port-Based, static VLAN*

Protocol: *Protocol-Based, static VLAN*

Dynamic: *Port-Based, temporary VLAN learned through GVRP (Refer to chapter 3, “GVRP” in this guide.)*

Voice: *Indicates whether a (port-based) VLAN is configured as a voice VLAN. Refer to “Voice VLANs” on page 2-55.*

Jumbo: *Indicates whether a VLAN is configured for Jumbo packets. For more on jumbos, refer to the chapter titled “Port Traffic Controls” in the Management and Configuration Guide for your switch.*

Port Information: *Lists the ports configured as members of the VLAN.*

DEFAULT: *Shows whether a port is a tagged or untagged member of the listed VLAN.*

Unknown VLAN: *Shows whether the port can become a dynamic member of an unknown VLAN for which it receives an advertisement. GVRP must be enabled to allow dynamic joining to occur. Refer to table 3-1 on page 3-8.*

Status: *Shows whether the port is participating in an active link.*

```
ProCurve(config)# show vlans 22
Status and Counters - VLAN Information - Ports - VLAN 22
 802.1Q VLAN ID : 22
 Name : VLAN22
 Status : Port-based
 Voice : Yes
 Jumbo : No
```

Port Information	Mode	Unknown VLAN	Status
A12	Untagged	Learn	Up
A13	Untagged	Learn	Up
A14	Untagged	Learn	Up
A15	Untagged	Learn	Down
A16	Untagged	Learn	Up
A17	Untagged	Learn	Up
A18	Untagged	Learn	Up

Figure 2-21. Example of “Show VLAN” for a Specific Static VLAN

Show VLAN lists this data when GVRP is enabled and at least one port on the switch has dynamically joined the designated VLAN.

```
ProCurve# show vlans 33
Status and Counters - VLAN Information - Ports - VLAN 33
 802.1Q VLAN ID : 33
 Name : GVRP_33
 Status : Dynamic
 Voice : No
 Jumbo : No
```

Port Information	DEFAULT	Unknown VLAN	Status
A6	Auto	Learn	Up

Figure 2-22. Example of “Show VLAN” for a Specific Dynamic VLAN

Changing the Number of VLANs Allowed on the Switch. In the default VLAN configuration, the switch allows a maximum of 256 VLANs. You can specify any value from 1 to 2048.

Syntax: max-vlans < 1-2048 >

*Specifies the maximum number of VLANs to allow. (If GVRP is enabled, this setting includes any dynamic VLANs on the switch.) As part of implementing a new setting, you must execute a **write memory** command (to save the new value to the startup-config file) and then reboot the switch.*

Note: *If multiple VLANs exist on the switch, you cannot reset the maximum number of VLANs to a value smaller than the current number of VLANs.*

For example, to reconfigure the switch to allow 10 VLANs:

Note that you can execute these three steps at another time.

```
ProCurve(config)# max-vlans 10
Command will take effect after saving configuration and reboot.
ProCurve(config)# write memory
ProCurve(config)# boot
Device will be rebooted, do you want to continue [y/n]? y
```

Figure 2-23. Example of Command Sequence for Changing the Number of VLANs

Changing the Primary VLAN. In the default VLAN configuration, the port-based default VLAN (**DEFAULT_VLAN**) is the Primary VLAN. However, you can reassign the Primary VLAN to any port-based, static VLAN on the switch. (For more on the Primary VLAN, refer to “The Primary VLAN” on page 2-46.) To identify the current Primary VLAN and list the available VLANs and their respective VIDs, use **show vlans**.

Syntax: primary-vlan < vid | ascii-name-string >

Reassigns the Primary VLAN function. Re-assignment must be to an existing, port-based, static VLAN. (The switch will not reassign the Primary VLAN function to a protocol VLAN.) If you re-assign the Primary VLAN to a non-default VLAN, you cannot later delete that VLAN from the switch until you again re-assign the Primary VLAN to another port-based, static VLAN.

For example, if you wanted to reassign the Primary VLAN to VLAN 22 and rename the VLAN with “22-Primary” and display the result:

```
ProCurve(config)# primary-vlan 22
ProCurve(config)# vlan 22 name 22-Primary
ProCurve(config)# show vlans
```

Reassigns the Primary VLAN to VLAN 22.

Renames VLAN 22 to “22-Primary”.

Status and Counters - VLAN Information

Maximum VLANs to support : 8
Primary VLAN : 22-Primary
Management VLAN :

802.1Q	VLAN ID	Name	Status	Voice	Jumbo
1		DEFAULT_VLAN	Static	No	No
22		22-Primary	Static	No	No

Figure 2-24. Example of Reassigning Primary VLAN and Changing the VLAN Name

Creating a New Static VLAN (Port-Based or Protocol-Based)

Changing the VLAN Context Level. The **vlan < vid >** command operates in the global configuration context to either configure a static VLAN and/or take the CLI to the specified VLAN's context.

Syntax: **vlan < vid | ascii-name-string >**
[no] vlan < vid >

*If < vid > does not exist in the switch, this command creates a port-based VLAN with the specified < vid >. If the command does not include options, the CLI moves to the newly created VLAN context. If you do not specify an optional name, the switch assigns a name in the default format: **VLANn** where **n** is the < vid > assigned to the VLAN. If the VLAN already exists and you enter either the **vid** or the **ascii-name-string**, the CLI moves to the specified VLAN's context.*

*The **[no]** form of the command deletes the VLAN as follows:*

- *If one or more ports belong only to the VLAN to be deleted, the CLI notifies you that these ports will be moved to the default VLAN and prompts you to continue the deletion. For member ports that also belong to another VLAN, there is no “move” prompt.*

[protocol < ipx | ipv4 | ipv6 | arp | appletalk | sna | netbeui >]

*Configures a static, protocol VLAN of the specified type. If multiple protocols are configured in the VLAN, then the **[no]** form removes the specified protocol from the VLAN. If a protocol VLAN is configured with only one protocol type and you use the **[no]** form of this command to remove that protocol, the switch changes the protocol VLAN to a port-based VLAN if the VLAN does not have an untagged member port. (If an untagged member port exists on the protocol VLAN, you must either convert the port to a tagged member or remove the port from the VLAN before removing the last protocol type from the VLAN.)*

Note: *If you create an IPv4 protocol VLAN, you must also assign the ARP protocol option to the VLAN to provide IP address resolution. Otherwise, IP packets are not deliverable. A “Caution” message appears in the CLI if you configure IPv4 in protocol VLAN that does not already include the arp protocol option. The same message appears if you add or delete another protocol in the same VLAN.*

name < ascii-name-string >

When included in a **vlan** command for creating a new static VLAN, specifies a non-default VLAN name. Also used to change the current name of an existing VLAN. (Avoid spaces and the following characters in the <ascii-name-string> entry: @, #, \$, ^, &, *, (, and). To include a blank space in a VLAN name, enclose the name in single or double quotes ('...' or "...").

[voice]

Designates a VLAN for VoIP use. For more on this topic, refer to “Voice VLANs” on page 2-55.

For example, to create a new, port-based, static VLAN with a VID of 100:

```
ProCurve(config)# vlan 100
ProCurve(vlan-100)# show vlans
```

Status and Counters - VLAN Information

Maximum VLANs to support : 8
Primary VLAN : DEFAULT_VLAN
Management VLAN :

802.1Q	VLAN ID	Name	Status	Voice	Jumbo
1		DEFAULT_VLAN	Port-based	No	No
100		VLAN100	Port-based	No	No

Creates the new VLAN.

Shows the VLANs currently configured in the switch.

If this field is empty, a Secure Management VLAN is not configured in the switch. Refer to “The Secure Management VLAN” on page 2-47

Figure 2-25. Example of Creating a New, Port-Based, Static VLAN

To go to a different VLAN context level, such as to the default VLAN:

```
ProCurve(vlan-100)# vlan default_vlan
ProCurve(vlan-1) _
```

Deleting a VLAN . If ports B1-B5 belong to both VLAN 2 and VLAN 3, and ports B6-B10 belong to VLAN 3 only, then deleting VLAN 3 causes the CLI to prompt you to approve moving ports B6 - B10 to VLAN 1 (the default VLAN). (Ports B1-B5 are not moved because they still belong to another VLAN.)

```
ProCurve(config)# no vlan 3
The following ports will be moved to the default VLAN:
B6-B10
Do you want to continue? [y/n] y
ProCurve(config)#
```

Converting a Dynamic VLAN to a Static VLAN. Use this feature if you want to convert a dynamic, port-based VLAN membership to a static, port-based VLAN membership. This is necessary if you want to make the VLAN permanent on the switch.

Syntax: static-vlan < vlan-id >

*Converts a dynamic, port-based VLAN membership to a static, port-based VLAN membership. (Allows port-based VLANs only). For this command, < vlan-id > refers to the VID of the dynamic VLAN membership. (Use **show vlan** to help identify the VID you need to use.) This command requires that GVRP is running on the switch and a port is currently a dynamic member of the selected VLAN. After you convert a dynamic VLAN to static, you must configure the switch's per-port participation in the VLAN in the same way that you would for any static VLAN. (For GVRP and dynamic VLAN operation, refer to chapter 3, "GVRP" .)*

For example, suppose a dynamic VLAN with a VID of 125 exists on the switch. The following command converts the VLAN to a port-based, static VLAN.

```
ProCurve(config)# static-vlan 125
```

Configuring Static VLAN Per-Port Settings. The **vlan <vlan-id>** command, used with the options listed below, changes the name of an existing static VLAN and changes the per-port VLAN membership settings.

Note

You can use these options from the configuration level by beginning the command with **vlan < vid >**, or from the context level of the specific VLAN by just typing the command option.

Syntax: [no] vlan < vid >

tagged < port-list >

*Configures the indicated port(s) as **Tagged** for the specified VLAN. The "no" version sets the port(s) to either **No** or (if GVRP is enabled) to **Auto**.*

untagged < port-list >

*Configures the indicated port(s) as **Untagged** for the specified VLAN. The "no" version sets the port(s) to either **No** or (if GVRP is enabled) to **Auto**.*

`forbid < port-list >`

*Used in port-based VLANs to configures < port-list > as “forbidden” to become a member of the specified VLAN, as well as other actions. Does not operate with protocol VLANs. The “no” version sets the port(s) to either **No** or (if GVRP is enabled) to **Auto**. Refer to chapter 3, “GVRP”, in this guide.*

`auto < port-list >`

*Available if GVRP is enabled on the switch. Returns the per-port settings for the specified VLAN to **Auto** operation. Note that **Auto** is the default per-port setting for a static VLAN if GVRP is running on the switch. (For information on dynamic VLAN and GVRP operation, refer to chapter 3, “GVRP”, in this guide.)*

For example, suppose you have a VLAN named VLAN100 with a VID of 100, and all ports are set to **No** for this VLAN. To change the VLAN name to “**Blue_Team**” and set ports A1 - A5 to **Tagged**, you would use these commands:

```
ProCurve(config)# vlan 100 name Blue_Team
ProCurve(config)# vlan 100 tagged a1-a5
```

To move to the vlan 100 context level and execute the same commands:

```
ProCurve(config)# vlan 100
ProCurve(vlan-100)# name Blue_Team
ProCurve(vlan-100)# tagged a1-a5
```

Similarly, to change the tagged ports in the above examples to **No** (or **Auto**, if GVRP is enabled), you could use either of the following commands.

At the global config level, use:

```
ProCurve(config)# no vlan 100 tagged a1-a5
```

- or -

At the VLAN 100 context level, use:

```
ProCurve(vlan-100)# no tagged a1-a5
```

Note

You cannot use these commands with dynamic VLANs. Attempting to do so results in the message “**VLAN already exists.**” and no change occurs.

Web: Viewing and Configuring VLAN Parameters

In the web browser interface you can do the following:

- Add VLANs
- Rename VLANs
- Remove VLANs
- Configure VLAN tagging mode per-port
- Configure GVRP mode
- Select a new Primary VLAN

To configure other static VLAN port parameters, you will need to use either the CLI or the menu interface (available by Telnet from the web browser interface).

1. Click on the Configuration tab.
2. Click on **[Vlan Configuration]**.
3. Click on **[Add/Remove VLANs]**.

For web-based Help on how to use the web browser interface screen, click on the **[?]** button provided on the web browser screen.

802.1Q VLAN Tagging

General Applications:

- The switch requires VLAN tagging on a given port if more than one VLAN of the same type uses the port. When a port belongs to two or more VLANs of the same type, they remain as separate broadcast domains and cannot receive traffic from each other without routing. (If multiple, *non-routable* VLANs exist in the switch—such as NETbeui protocol VLANs— then they cannot receive traffic from each other under any circumstances.)
- The switch requires VLAN tagging on a given port if the port will be receiving inbound, tagged VLAN traffic that should be forwarded. Even if the port belongs to only one VLAN, it forwards inbound tagged traffic only if it is a tagged member of that VLAN.
- If the only authorized, inbound VLAN traffic on a port arrives untagged, then the port must be an untagged member of that VLAN. This is the case where the port is connected to a non 802.1Q-compliant device or is assigned to only one VLAN.

For example, if port 7 on an 802.1Q-compliant switch is assigned to only the Red VLAN, the assignment can remain “untagged” because the port will forward traffic only for the Red VLAN. However, if both the Red and Green VLANs are assigned to port 7, then at least one of those VLAN assignments must be “tagged” so that Red VLAN traffic can be distinguished from Green VLAN traffic. Figure 2-26 shows this concept:

Figure 2-26. Example of Tagged and Untagged VLAN Port Assignments

- In switch X:
 - VLANs assigned to ports X1 - X6 can all be untagged because there is only one VLAN assignment per port. Red VLAN traffic will go out only the Red ports; Green VLAN traffic will go out only the Green ports, and so on. Devices connected to these ports do not have to be 802.1Q-compliant.
 - However, because both the Red VLAN and the Green VLAN are assigned to port X7, at least one of the VLANs must be tagged for this port.
- In switch Y:
 - VLANs assigned to ports Y1 - Y4 can all be untagged because there is only one VLAN assignment per port. Devices connected to these ports do not have to be 802.1Q-compliant.
 - Because both the Red VLAN and the Green VLAN are assigned to port Y5, at least one of the VLANs must be tagged for this port.
- In both switches: The ports on the link between the two switches must be configured the same. As shown in figure 2-26 (above), the Red VLAN must be untagged on port X7 and Y5 and the Green VLAN must be tagged on port X7 and Y5, or vice-versa.

Note

Each 802.1Q-compliant VLAN must have its own unique VID number, and that VLAN *must* be given the same VID in every device in which it is configured. That is, if the Red VLAN has a VID of 10 in switch X, then 10 must also be used for the Red VID in switch Y.

Figure 2-27. Example of VLAN ID Numbers Assigned in the VLAN Names Screen

VLAN tagging gives you several options:

- Since the purpose of VLAN tagging is to allow multiple VLANs on the same port, any port that has only one VLAN assigned to it can be configured as “Untagged” (the default) if the authorized inbound traffic for that port arrives untagged.
- Any port with two or more VLANs of the same type can have one such VLAN assigned as “Untagged”. All other VLANs of the same type must be configured as “Tagged”. That is:

Port-Based VLANs	Protocol VLANs
A port can be a member of one untagged, port-based VLAN. All other port-based VLAN assignments for that port must be tagged.	A port can be an untagged member of one protocol-based VLAN of each protocol type. When assigning a port to multiple, protocol-based VLANs sharing the same type, the port can be an untagged member of only one such VLAN.
A port can be a tagged member of any port-based VLAN. See above.	A port can be a tagged member of any protocol-based VLAN. See above.
Note: A given VLAN <i>must</i> have the same VID on all 802.1Q-compliant devices in which the VLAN occurs. Also, the ports connecting two 802.1Q devices should have identical VLAN configurations.	

- If all end nodes on a port comply with the 802.1Q standard and are configured to use the correct VID, then, you can configure all VLAN assignments on a port as “Tagged” if doing so either makes it easier to manage your VLAN assignments, or if the authorized, inbound traffic for all VLANs on the port will be tagged.

For a summary and flowcharts of untagged and tagged VLAN operation on inbound traffic, refer to the following under “VLAN Operating Rules” on pages 2-14 through 2-17:

- “Inbound Tagged Packets”
- “Untagged Packet Forwarding” and figure 2-7
- “Tagged Packet Forwarding” and figure 2-8

Example. In the following network, switches X and Y and servers S1, S2, and the AppleTalk server are 802.1Q-compliant. (Server S3 could also be 802.1Q-compliant, but it makes no difference for this example.) This network includes both protocol-based (AppleTalk) VLANs and port-based VLANs.

Figure 2-28. Example of Networked 802.1Q-Compliant Devices with Multiple VLANs on Some Ports

- The VLANs assigned to ports X4 - X6, Y2 - Y5 can all be untagged because there is only one VLAN assigned per port.
- Port X1 has two AppleTalk VLANs assigned, which means that one VLAN assigned to this port can be untagged and the other must be tagged.
- Ports X2 and Y1 have two port-based VLANs assigned, so one can be untagged and the other must be tagged on both ports.
- Ports X3 and Y6 have two port-based VLANs and one protocol-based VLAN assigned. Thus, one port-based VLAN assigned to this port can be untagged and the other must be tagged. Also, since these two ports share the same link, their VLAN configurations must match.

Switch X					Switch Y				
Port	AT-1 VLAN	AT-2 VLAN	Red VLAN	Green VLAN	Port	AT-1 VLAN	AT-2 VLAN	Red VLAN	Green VLAN
X1	Untagged	Tagged	No*	No*	Y1	No*	No*	Untagged	Tagged
X2	No*	No*	Untagged	Tagged	Y2	No*	No*	No*	Untagged
X3	No*	Untagged	Untagged	Tagged	Y3	No*	Untagged	No*	No*
X4	No*	No*	No*	Untagged	Y4	No*	No*	No*	Untagged
X5	No*	No*	Untagged	No*	Y5	No*	No*	Untagged	No*
X6	Untagged	No*	No*	No*	Y6	No	Untagged	Untagged	Tagged
*“No” means the port is not a member of that VLAN. For example, port X3 is not a member of the Red VLAN and does not carry Red VLAN traffic. Also, if GVRP were enabled (port-based only), “Auto” would appear instead of “No”.									

Note

VLAN configurations on ports connected by the same link must match. Because ports X2 and Y5 are opposite ends of the same point-to-point connection, both ports must have the same VLAN configuration; that is, both ports configure the Red VLAN as “Untagged” and the Green VLAN as “Tagged”.

Special VLAN Types

VLAN Support and the Default VLAN

In the factory default configuration, VLAN support is enabled and all ports on the switch belong to the port-based, default VLAN (named `DEFAULT_VLAN`). This places all ports in the switch into one physical broadcast domain. In the factory-default state, the default VLAN is also the *Primary* VLAN.

You can partition the switch into multiple virtual broadcast domains by configuring one or more additional VLANs and moving ports from the default VLAN to the new VLANs. (The switch supports up to 2048 (vids numbered up to 4094) static and dynamic VLANs.) You can change the name of the default VLAN, but you cannot change the default VLAN's VID (which is always "1"). Although you can remove all ports from the default VLAN (by placing them in another port-based VLAN), this VLAN is always present; that is, you cannot delete it from the switch.

For details on port VLAN settings, refer to "Configuring Static VLAN Per-Port Settings" on page 2-38

The Primary VLAN

Because certain features and management functions run on only one VLAN in the switch, and because DHCP and Bootp can run per-VLAN, there is a need for a dedicated VLAN to manage these features and ensure that multiple instances of DHCP or Bootp on different VLANs do not result in conflicting configuration values for the switch. The *Primary* VLAN is the VLAN the switch uses to run and manage these features and data. In the factory-default configuration, the switch designates the default VLAN (`DEFAULT_VLAN`; VID = 1) as the Primary VLAN. However, to provide more control in your network, you can designate another static, port-based VLAN as primary. To summarize, *designating a non-default VLAN as primary* means that:

- The switch reads DHCP responses on the Primary VLAN instead of on the default VLAN. (This includes such DHCP-resolved parameters as the TimeP server address, Default TTL, and IP addressing—including the Gateway IP address—when the switch configuration specifies DHCP as the source for these values.)
- The default VLAN continues to operate as a standard VLAN (except, as noted above, you cannot delete it or change its VID).

- Any ports not specifically assigned to another VLAN will remain assigned to the Default VLAN, regardless of whether it is the Primary VLAN.

Candidates for Primary VLAN include any static, port-based VLAN currently configured on the switch. (Protocol-Based VLANs and dynamic—GVRP-learned—VLANs that have not been converted to a static VLAN cannot be the Primary VLAN.) To display the current Primary VLAN, use the CLI **show vlan** command.

Note

If you configure a non-default VLAN as the Primary VLAN, you cannot delete that VLAN unless you first select a different VLAN to serve as primary.

If you manually configure a gateway on the switch, it ignores any gateway address received via DHCP or Bootp.

To change the Primary VLAN configuration, refer to “Changing the Primary VLAN” on page 2-35.

The Secure Management VLAN

Configuring a secure Management VLAN creates an isolated network for managing the ProCurve switches that support this feature. (As of December, 2005, the Secure Management VLAN feature is available on these ProCurve switches:

- | | |
|--------------------------|--------------------------|
| ■ Switch 8212zl | ■ Series 4100gl switches |
| ■ Series 6400cl switches | ■ Series 3500yl switches |
| ■ Switch 6200yl | ■ Series 3400cl switches |
| ■ Switch 6108 | ■ Switch 2900 |
| ■ Series 5400zl switches | ■ Series 2800 switches |
| ■ Series 5300xl switches | ■ Series 2600 switches |
| ■ Series 4200vl switches | |

If you configure a Secure Management VLAN, access to the VLAN and to the switch’s management functions (Menu, CLI, and web browser interface) is available only through ports configured as members.

- Multiple ports on the switch can belong to the Management VLAN. This allows connections for multiple management stations you want to have access to the Management VLAN, while at the same time allowing Management VLAN links between switches configured for the same Management VLAN.

- Only traffic from the Management VLAN can manage the switch, which means that only the workstations and PCs connected to ports belonging to the Management VLAN can manage and reconfigure the switch.

Figure 2-29 illustrates use of the Management VLAN feature to support management access by a group of management workstations.

Figure 2-29. Example of Potential Security Breaches

In figure 2-30, Workstation 1 has management access to all three switches through the Management VLAN, while the PCs do not. This is because configuring a switch to recognize a Management VLAN automatically excludes attempts to send management traffic from any other VLAN.

Figure 2-30. Example of Management VLAN Control in a LAN

Table 2-7. VLAN Membership in Figure 2-30

Switch	A1	A3	A6	A7	B2	B4	B5	B9	C2	C3	C6	C8
Management VLAN (VID = 7)	Y	N	N	Y	Y	Y	N	N	Y	N	N	N
Marketing VLAN (VID = 12)	N	N	N	N	N	N	N	N	N	Y	Y	Y
Shipping Dept. VLAN (VID = 20)	N	Y	Y	N	N	N	N	N	N	N	N	N
DEFAULT-VLAN (VID = 1)	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y

Preparation

1. Determine a VID and VLAN name suitable for your Management VLAN.
2. Plan your Management VLAN topology to use ProCurve switches that support this feature. (Refer to page 2-47.) The ports belonging to the Management VLAN should be only the following:
 - Ports to which you will connect authorized management stations (such as Port A7 in figure 2-30.)
 - Ports on one switch that you will use to extend the Management VLAN to ports on other ProCurve switches (such as ports A1 and B2 or B4 and C2 in figure 2-30 on page 2-49.).

Hubs dedicated to connecting management stations to the Management VLAN can also be included in the above topology. Note that any device connected to a hub in the Management VLAN will also have Management VLAN access.

3. Configure the Management VLAN on the selected switch ports.
4. Test the management VLAN from all of the management stations authorized to use the Management VLAN, including any SNMP-based network management stations. Ensure that you include testing any Management VLAN links between switches.

Note

If you configure a Management VLAN on a switch by using a Telnet connection through a port that is not in the Management VLAN, then you will lose management contact with the switch if you log off your Telnet connection or execute **write memory** and **reboot** the switch.

Configuration

Syntax: [no] management-vlan < vlan-id / vlan-name >

*Configures an existing VLAN as the management VLAN. The **no** form disables the management VLAN and returns the switch to its default management operation. Default: Disabled. In this case, the VLAN returns to standard VLAN operation.*

For example, suppose you have already configured a VLAN named **My_VLAN** with a VID of 100. Now you want to configure the switch to do the following:

- Use **My_VLAN** as a Management VLAN (tagged, in this case) to connect port A1 on switch “A” to a management station. (The management station includes a network interface card with 802.1Q tagged VLAN capability.)
- Use port A2 to extend the Management VLAN to port B1 (which is already configured as a tagged member of **My_VLAN**) on an adjacent Procurve switch that supports the Management VLAN feature.

Figure 2-31. Illustration of Configuration Example

```
ProCurve (config)# management-vlan 100
ProCurve (config)# vlan 100 tagged a1
ProCurve (config)# vlan 100 tagged a2
```

Using DHCP to Obtain an IP Address

You can use DHCP to obtain an IPv4 address for your Management VLAN or a client on that VLAN. The following examples illustrate when an IP address will be received from the DHCP server.

1. If Blue_VLAN is configured as the Management VLAN and the DHCP server is also on Blue_VLAN, Blue_VLAN receives an IP address. Because DHCP Relay does not forward onto or off of the Management VLAN, devices on Red_VLAN cannot get an IP address from the DHCP server on Blue_VLAN (Management VLAN) and Red_VLAN does not receive an IP address. See figure 2-32.

Figure 2-32. Example of DHCP Server on Management VLAN

2. If Red_VLAN is configured as the Management VLAN and the DHCP server is on Blue_VLAN, Blue_VLAN receives an IP address but Red_VLAN does not. See figure 2-33.

Figure 2-33. Example of DHCP Server on Different VLAN from the Management VLAN

3. If no Management VLAN is configured, both Blue_VLAN and Red_VLAN receive IP addresses. See figure 2-34.

Figure 2-34. Example of no Management VLANs Configured

4. If Red_VLAN is configured as the Management VLAN and the client is on Red_VLAN, but the DHCP server is on Blue_VLAN, the client will not receive an IP address. See figure 2-35.

Figure 2-35. Example of Client on Different Management VLAN from DHCP Server

5. If Blue_VLAN is configured as the Management VLAN, the client is on Blue_VLAN, and the DHCP server is on Blue_VLAN, the client receives an IP address.

Figure 2-36. Example of DHCP Server and Client on the Management VLAN

Deleting the Management VLAN

You can disable the Secure Management feature without deleting the VLAN itself. For example, either of the following commands disables the Secure Management feature in the above example:

```
ProCurve (config)# no management-vlan 100  
ProCurve (config)# no management-vlan my_vlan
```

Operating Notes for Management VLANs

- Use only a static, port-based VLAN for the Management VLAN.
- The Management VLAN does not support IGMP operation.
- Routing between the Management VLAN and other VLANs is not allowed.
- If there are more than 25 VLANs configured on the switch, reboot the switch after configuring the management VLAN.
- If you implement a Management VLAN in a switch mesh environment, all meshed ports on the switch will be members of the Management VLAN.
- Only one Management-VLAN can be active in the switch. If one Management-VLAN VID is saved in the startup-config file and you configure a different VID in the running-config file, the switch uses the running-config version until you either use the **write-memory** command or reboot the switch.
- During a Telnet session to the switch, if you configure the Management-VLAN to a VID that excludes the port through which you are connected to the switch, you will continue to have access only until you terminate the session by logging out or rebooting the switch.
- During a web browser session to the switch, if you configure the Management-VLAN to a VID that excludes the port through which you are connected to the switch, you will continue to have access only until you close the browser session or rebooting the switch.

Note

The Management-VLAN feature does not control management access through a direct connection to the switch's serial port.

- Enabling Spanning Tree where there are multiple links using separate VLANs, including the Management VLAN, between a pair of switches, Spanning Tree will force the blocking of one or more links. This may include the link carrying the Management VLAN, which will cause loss of management access to some devices. This can also occur where meshing is configured and the Management VLAN is configured on a separate link.

- **Monitoring Shared Resources:** The Management VLAN feature shares internal switch resources with several other features. The switch provides ample resources for all features. However, if the internal resources become fully subscribed, the Management VLAN feature cannot be configured until the necessary resources are released from other uses. For information on determining the current resource availability and usage, refer to the appendix titled “Monitoring Resources” in the *Management and Configuration Guide* for your switch.

Figure 2-37. Example of Inadvertently Blocking a Management VLAN Link by Implementing Spanning Tree

Voice VLANs

Configuring voice VLANs separates voice traffic from data traffic and shields your voice traffic from broadcast storms. This section describes how to configure the switch for voice VLAN operation.

Operating Rules for Voice VLANs

- You must statically configure voice VLANs. GVRP and dynamic VLANs do not support voice VLAN operation.
- Configure all ports in a voice VLAN as tagged members of the VLAN. This ensures retention of the QoS (Quality of Service) priority included in voice VLAN traffic moving through your network.
- If a telephone connected to a voice VLAN includes a data port used for connecting other networked devices (such as PCs) to the network, then you must configure the port as a tagged member of the voice VLAN and a tagged or untagged member of the data VLAN you want the other networked device to use.

Components of Voice VLAN Operation

- **Voice VLAN(s):** Configure one or more voice VLANs on the switch. Some reasons for having multiple voice VLANs include:
 - Employing telephones with different VLAN requirements
 - Better control of bandwidth usage
 - Segregating telephone groups used for different, exclusive purposes

Where multiple voice VLANs exist on the switch, you can use routing to communicate between telephones on different voice VLANs. .

- **Tagged/Untagged VLAN Membership:** If the appliances using a voice VLAN transmit tagged VLAN packets, then configure the member ports as tagged members of the VLAN. Otherwise, configure the ports as untagged members.

Voice VLAN QoS Prioritizing (Optional)

Without configuring the switch to prioritize voice VLAN traffic, one of the following conditions applies:

- If the ports in a voice VLAN are not tagged members, then the switch forwards all traffic on that VLAN at “normal” priority.
- If the ports in a voice VLAN are tagged members, then the switch forwards all traffic on that VLAN at whatever priority the traffic has when received inbound on the switch.

Using the switch’s QoS VLAN-ID (VID) Priority option, you can change the priority of voice VLAN traffic moving through the switch. If all port memberships on the voice VLAN are tagged, the priority level you set for voice VLAN traffic is carried to the next device. With all ports on the voice VLAN configured as tagged members, you can enforce a QoS priority policy moving through the switch and through your network. To set a priority on a voice VLAN, use the following command:

Syntax: `vlan < vid > qos priority < 0 - 7 >`

The qos priority default setting is 0 (normal), with 1 as the lowest priority and 7 as the highest priority.

For example, if you configured a voice VLAN with a VID of 10, and wanted the highest priority for all traffic on this VLAN, you would execute the following command:

```
ProCurve(config) # vlan 10 qos priority 7
ProCurve (config) # write memory
```

Note that you also have the option of resetting the DSCP (DiffServe Code-point) on tagged voice VLAN traffic moving through the switch. For more on this and other QoS topics, refer to the chapter titled “Quality of Service (QoS): Managing Bandwidth More Effectively” in this guide.

Voice VLAN Access Security

You can use port security configured on an individual port or group of ports in a voice VLAN. That is, you can allow or deny access to a phone having a particular MAC address. Refer to chapter titled “Configuring and Monitoring Port Security” in the *Access Security Guide* for your switch.

Note

MAC authentication is not recommended in voice VLAN applications.

Effect of VLANs on Other Switch Features

Spanning Tree Operation with VLANs

Depending on the spanning-tree option configured on the switch, the spanning-tree feature may operate as a single instance across all ports on the switch (regardless of VLAN assignments) or multiple instance on a per-VLAN basis. For single-instance operation, this means that if redundant physical links exist between the switch and another 802.1Q device, all but one link will be blocked, regardless of whether the redundant links are in separate VLANs. In this case you can use port trunking to prevent Spanning Tree from unnecessarily blocking ports (and to improve overall network performance). For multiple-instance operation, physically redundant links belonging to different VLANs can remain open. Refer to chapter 4, “Multiple Instance Spanning-Tree Operation” .

Note that Spanning Tree operates differently in different devices. For example, in the (obsolete, non-802.1Q) ProCurve Switch 2000 and the ProCurve Switch 800T, Spanning Tree operates on a per-VLAN basis, allowing redundant physical links as long as they are in separate VLANs.

IP Interfaces

There is a one-to-one relationship between a VLAN and an IP network interface. Since the VLAN is defined by a group of ports, the state (up/down) of those ports determines the state of the IP network interface associated with that VLAN. When a port-based VLAN or an IPv4 or IPv6 protocol-based VLAN comes up because one or more of its ports is up, the IP interface for that VLAN is also activated. Likewise, when a VLAN is deactivated because all of its ports are down, the corresponding IP interface is also deactivated.

VLAN MAC Address

The switches covered by this guide have one unique MAC address for all of their VLAN interfaces. You can send an 802.2 test packet to this MAC address to verify connectivity to the switch. Likewise, you can assign an IP address to the VLAN interface, and when you Ping that address, ARP will resolve the IP address to this single MAC address. In a topology where a switch has multiple VLANs and must be connected to a device having a single forwarding database, such as the Switch 4000M, some cabling restrictions apply. For more on this topic, refer to “Multiple VLAN Considerations” on page 2-18.

Port Trunks

When assigning a port trunk to a VLAN, all ports in the trunk are automatically assigned to the same VLAN. You cannot split trunk members across multiple VLANs. Also, a port trunk is tagged, untagged, or excluded from a VLAN in the same way as for individual, untrunked ports.

Port Monitoring

If you designate a port on the switch for network monitoring, this port will appear in the Port VLAN Assignment screen and can be configured as a member of any VLAN. For information on how broadcast, multicast, and unicast packets are tagged inside and outside of the VLAN to which the monitor port is assigned, refer to the section titled “VLAN-Related Problems” in the “Troubleshooting” appendix of the *Management and Configuration Guide* for your switch.

Jumbo Packet Support

Jumbo packet support is enabled per-VLAN and applies to all ports belonging to the VLAN. For more information, refer to the chapter titled “Port Traffic Controls” in the *Management and Configuration Guide* for your switch.

VLAN Restrictions

- A port must be a member of at least one VLAN. In the factory default configuration, all ports are assigned to the default VLAN (DEFAULT_VLAN; VID = 1).
- A port can be a member of one untagged, port-based VLAN. All other port-based VLAN assignments for that port must be tagged. (The “Untagged” designation enables VLAN operation with non 802.1Q-compliant devices.)
- A port can be an untagged member of one protocol-based VLAN of each protocol type. When assigning a port to multiple, protocol-based VLANs sharing the same type, the port can be an untagged member of only one such VLAN.
- With routing enabled on the switch, the switch can route traffic between:
 - Multiple, port-based VLANs
 - A port-based VLAN and an IPv4 protocol-based VLAN
 - A port-based VLAN and an IPv6 protocol-based VLAN
 - An IPv4 protocol-based VLAN and an IPv6 protocol VLAN.

Other, routable, protocol-based VLANs must use an external router to move traffic between VLANs. With routing disabled, all routing between VLANs must be through an external router.

- Prior to deleting a static VLAN, you must first re-assign all ports in the VLAN to another VLAN. You can use the **no vlan < vid >** command to delete a static VLAN. For more information, refer to “Creating a New Static VLAN (Port-Based or Protocol-Based) Changing the VLAN Context Level” on page 2-36.

Migrating Layer 3 VLANs Using VLAN MAC Configuration

ProCurve routing switches provide an easy way to maintain Layer 3 VLAN configurations when you migrate distribution routers in a network configuration that is not centrally managed. By following the procedure described in this section, you can upgrade to ProCurve routing switches without stopping the operation of attached hosts that use existing routers as their default gateway to route traffic between VLANs. You can achieve seamless VLAN migration by configuring the MAC address of the previously installed router on the VLAN interfaces of a ProCurve routing switch.

VLAN MAC Address Reconfiguration

The ProCurve switches covered by this guide use one unique MAC address for all VLAN interfaces. If you assign an IP address to a VLAN interface, ARP resolves the IP address to the MAC address of the routing switch for all incoming packets.

The Layer 3 VLAN MAC Configuration feature allows you to reconfigure the MAC address used for VLAN interfaces using the CLI. Packets addressed to the reconfigured Layer 3 MAC address, such as ARP and IP data packets, are received and processed by the ProCurve routing switch.

Packets transmitted from the routing switch (packets originating from the router and forwarded packets) use the original ProCurve MAC address as the source MAC address in Ethernet headers.

ARP reply packets use the reconfigured MAC address in both the:

- ARP Sender MAC address field.
- Source MAC address field in the Ethernet frame header

When you reconfigure the MAC address on a VLAN interface, you may also specify a keepalive timeout to transmit heartbeat packets that advertise the new MAC address.

By configuring the MAC address of the previously installed router as the MAC address of each VLAN interface on a ProCurve switch, you can swap the physical port of a router to the ProCurve switch after the switch has been properly configured in the network.

Handling Incoming and Outgoing VLAN Traffic

Incoming VLAN data packets and ARP requests are received and processed on the routing switch according to the MAC address of the previously installed router that is configured for each VLAN interface.

Outgoing VLAN traffic uses the MAC address of the ProCurve switch as the source MAC address in packet headers. The MAC address configured on VLAN interfaces is not used on outbound VLAN traffic.

When the routing switch receives an ARP request for the IP address configured on a VLAN interface, the ARP reply uses the reconfigured MAC address in both the:

- ARP Sender MAC address field
- Source MAC address field in the Ethernet frame header.

When proxy ARP is enabled on a VLAN interface, the "gracious" ARP reply sent for an ARP request received from VLAN devices located outside the directly connected IP subnets also contains the reconfigured MAC address in the:

- ARP Sender MAC address field
- Source MAC address field in the Ethernet frame header.

To hosts in the network, VLAN traffic continues to be routed (using the reconfigured MAC address as destination address), but outbound VLAN traffic appears to be sent from another router (using the ProCurve MAC address as source address) attached to the same subnet. Although it appears as an asymmetric path to network hosts, the MAC address configuration feature enables Layer 3 VLAN migration. (A successful VLAN migration is achieved because the hosts do not verify that the source MAC address and the destination MAC address are the same when communicating with the routing switch.)

Sending Heartbeat Packets with a Configured MAC Address

On the VLAN interfaces of a routing switch, the user-defined MAC address only applies to inbound traffic. As a result, any connected switches need to learn the new address that is included in the Ethernet frames of outbound VLAN traffic transmitted from the routing switch.

If a connected switch does not have the newly configured MAC address of the routing switch as a destination in its MAC address table, it floods packets to all of its ports until a return stream allows the switch to learn the correct destination address. As a result, the performance of the switch is degraded as it tries to send Ethernet packets to an unknown destination address.

To allow connected switches to learn the user-configured MAC address of a VLAN interface, the ProCurve routing switch can send periodic heartbeat-like Ethernet packets. The Ethernet packets contain the configured MAC address as the source address in the packet header. IP multicast packets or Ethernet service frames are preferred because they do not interrupt the normal operation of client devices connected on the segment.

Because the aging time of destination addresses in MAC address tables varies on network devices, you must also configure a time interval to use for sending heartbeat packets.

Heartbeat packets are sent at periodic intervals with a specific ProCurve unicast MAC address in destination field. This MAC address is assigned to ProCurve and is not used by other non-ProCurve routers. Because the heartbeat packet contains a unicast MAC address, it does not interrupt host operation. Even if you have multiple ProCurve switches connected to the network, there is no impact on network performance because each switch sends heartbeat packets with its configured MAC address as the destination address.

The format of a heartbeat packet is an extended Ethernet OUI frame with an extended OUI Ethertype (88B7) and a new protocol identifier in the 5-octet protocol identifier field.

Configuring a VLAN MAC Address with Heartbeat Interval

When installing ProCurve routing switches in the place of existing routers in a network configuration, you can achieve Layer 3 VLAN migration by using the **ip-recv-mac-address** command at the VLAN configuration level to:

- Configure the MAC address of the previously installed router on each VLAN interface of a ProCurve routing switch.
- Optionally configure the time interval to use for sending heartbeat packets with the configured MAC address.

Syntax: [no] ip-recv-mac-address <mac-address> [interval <seconds>]

ip-recv-mac-address <mac-address>

*Configures a VLAN interface with the specified MAC address. Enter the **no** version of the command to remove the configured MAC address and return to the original MAC address of the ProCurve switch.*

interval <seconds>

(Optional) Configures the time interval (in seconds) used between transmissions of heartbeat packets to all network devices configured on the VLAN. Valid values are from one to 255 seconds. The default is 60 seconds.

Operating Notes

- The **ip-recv-mac-address** command allows you to configure only one MAC address for a specified VLAN. If you re-enter the command to configure another MAC address, the previously configured MAC address is overwritten.
- Enter the **no** form of the command to remove a configured MAC address and restore the default MAC address of the ProCurve switch.
- When you configure a VLAN MAC address, you may also specify a heartbeat interval. The **interval** <seconds> parameter is optional.
- After you configure a VLAN MAC address:
 - IP router and MAC ARP replies to other VLAN devices contain the user-defined MAC address as the Ethernet sender hardware address.
 - Outbound VLAN traffic contains the ProCurve MAC address, not the configured MAC address, as the source MAC address in packet headers.

- Immediately after you configure a VLAN MAC address or remove a configured MAC address, a gratuitous ARP message is broadcast on the connected segment to announce the change of the IP-to-MAC address binding to all connected IP-based equipment.
- A configured VLAN MAC address supports proxy ARP and gracious ARP.
- A new MIB variable, **ifRcvAddressTable**, is introduced to support VLAN MAC configuration.
- You cannot configure a VLAN MAC address using the web browser or menu interface. You must use the CLI.

Example

The following example shows how to configure a MAC address on VLAN 101.

```
ProCurve# configure terminal
ProCurve(config)# vlan 101
ProCurve(vlan-101)# ip-recv-mac-address 0060b0-e9a200
interval 100
```

Verifying a VLAN MAC Address Configuration

To verify the configuration of Layer 3 MAC addresses on the VLAN interfaces of a switch, enter the **show ip-recv-mac-address** command.

```
ProCurve# show ip-recv-mac-address

VLAN L3-Mac-Address Table

VLAN          L3-Mac-Address  Timeout
-----
DEFAULT_VLAN  001635-024467   60
VLAN2         001635-437529   100
```

Overview

This chapter describes GVRP and how to configure it with the switch's built-in interfaces, and assumes an understanding of VLANs, which are described in chapter 2, "Static Virtual LANs (VLANs)".

For general information on how to use the switch's built-in interfaces, refer to these chapters in the *Management and Configuration Guide* for your switch:

- Chapter 3, "Using the Menu Interface"
- Chapter 4, "Using the Command Line Interface (CLI)"
- Chapter 5, "Using the Web Browser Interface"
- Chapter 6, "Switch Memory and Configuration"

GVRP—GARP VLAN Registration Protocol—is an application of the Generic Attribute Registration Protocol—GARP. GVRP is defined in the IEEE 802.1Q standard, and GARP is defined in the IEEE 802.1D-1998 standard.

Note

To understand and use GVRP you must have a working knowledge of 802.1Q VLAN tagging. (Refer to chapter 2, “Static Virtual LANs (VLANs)” .)

GVRP uses “GVRP Bridge Protocol Data Units” (“GVRP BPDUs”) to “advertise” static VLANs. In this manual, a GVRP BPDU is termed an *advertisement*. Advertisements are sent outbound from ports on a switch to the devices directly connected to those ports.

GVRP enables the switch to dynamically create 802.1Q-compliant VLANs on links with other devices running GVRP. This enables the switch to automatically create VLAN links between GVRP-aware devices. (A GVRP link can include intermediate devices that are not GVRP-aware.) This operation reduces the chances for errors in VLAN configuration by automatically providing VLAN ID (VID) consistency across the network. That is, you can use GVRP to propagate VLANs to other GVRP-aware devices instead of manually having to set up VLANs across your network. After the switch creates a dynamic VLAN, you can optionally use the CLI **static <vlan-id>** command to

convert it to a static VLAN or allow it to continue as a dynamic VLAN for as long as needed. You can also use GVRP to dynamically enable port membership in static VLANs configured on a switch.

Note:

On the switches covered in this guide, GVRP can be enabled only if **max vlans** is set to no more than 256 VLANs.

General Operation

When GVRP is enabled on a switch, the VID for any static VLANs configured on the switch is *advertised* (using BPDUs—Bridge Protocol Data Units) out all ports, regardless of whether a port is up or assigned to any particular VLAN. A GVRP-aware port on another device that receives the advertisements over a link can dynamically join the advertised VLAN.

A dynamic VLAN (that is, a VLAN learned through GVRP) is tagged on the port on which it was learned. Also, a GVRP-enabled port can forward an advertisement for a VLAN it learned about from other ports on the same switch (internal source), but the forwarding port will not itself join that VLAN until an advertisement for that VLAN is received through a link from another device (external source) on that specific port

Figure 3-1. Example of Forwarding Advertisements and Dynamic Joining

Note that if a static VLAN is configured on at least one port of a switch, and that port has established a link with another device, then all other ports of that switch will send advertisements for that VLAN.

For example, in the following figure, Tagged VLAN ports on switch “A” and switch “C” advertise VLANs 22 and 33 to ports on other GVRP-enabled switches that can dynamically join the VLANs.

Figure 3-2. Example of GVRP Operation

Note

A port can learn of a dynamic VLAN through devices that are not aware of GVRP (Switch "B", above). VLANs must be disabled in GVRP-unaware devices to allow tagged packets to pass through.

A GVRP-aware port receiving advertisements has these options:

- If there is not already a static VLAN with the advertised VID on the receiving port, then dynamically create the VLAN and become a member.
- If the switch already has a static VLAN assignment with the same VID as in the advertisement, and the port is configured to **Auto** for that VLAN, then the port will dynamically join the VLAN and begin moving that VLAN's traffic. (For more detail on **Auto**, see "Per-Port Options for Dynamic VLAN Advertising and Joining" on page 3-9.)
- Ignore the advertisement for that VID.
- Don't participate in that VLAN.

Note also that a port belonging to a Tagged or Untagged static VLAN has these configurable options:

- Send VLAN advertisements, and also receive advertisements for VLANs on other ports and dynamically join those VLANs.
- Send VLAN advertisements, but ignore advertisements received from other ports.
- Avoid GVRP participation by not sending advertisements and dropping any advertisements received from other devices.

IP Addressing. A dynamic VLAN does not have an IP address, and moves traffic on the basis of port membership in VLANs. However, after GVRP creates a dynamic VLAN, you can convert it to a static VLAN. Note that it is then necessary to assign ports to the VLAN in the same way that you would for a static VLAN that you created manually. In the static state you can configure IP addressing on the VLAN and access it in the same way that you would any other static (manually created) VLAN.

Per-Port Options for Handling GVRP “Unknown VLANs”

An “unknown VLAN” is a VLAN that the switch learns of by receiving an advertisement for that VLAN on a port that is not already a member of that VLAN. If the port is configured to learn unknown VLANs, then the VLAN is dynamically created and the port becomes a tagged member of the VLAN. For example, suppose that in figure 3-2 (page 3-6), port 1 on switch “A” is connected to port 5 on switch “C”. Because switch “A” has VLAN 22 statically configured, while switch “C” does not have this VLAN statically configured (and does not “Forbid” VLAN 22 on port 5), VLAN 22 is handled as an “Unknown VLAN” on port 5 in switch “C”. Conversely, if VLAN 22 was statically configured on switch C, but port 5 was not a member, port 5 would become a member when advertisements for VLAN 22 were received from switch “A”.

When you enable GVRP on a switch, you have the per-port join-request options listed in table 3-1:

Table 3-1. Options for Handling “Unknown VLAN” Advertisements:

Unknown VLAN Mode	Operation
Learn (the Default)	Enables the port to become a member of any unknown VLAN for which it receives an advertisement. Allows the port to advertise other VLANs that have at least one other port on the same switch as a member.
Block	Prevents the port from joining any new dynamic VLANs for which it receives an advertisement. Allows the port to advertise other VLANs that have at least one other port as a member.
Disable	Causes the port to ignore and drop all GVRP advertisements it receives and also prevents the port from sending any GVRP advertisements.

The CLI **show gvrp** command and the menu interface VLAN Support screen show a switch's current GVRP configuration, including the Unknown VLAN settings.

```

ProCurve# show gvrp
GVRP support
Maximum VLANs to support : 8
GVRP Enabled : Yes
Port Type      | Unknown VLAN
-----+-----
A1  10/100TX  | Learn
A2  10/100TX  | Learn
A3  10/100TX  | Block
A4  10/100TX  | Block
A5  10/100TX  | Learn
A6  10/100TX  | Disable
A7  10/100TX  | Learn
A8  10/100TX  | Learn
.      .      .
.      .      .
.      .      .

```

GVRP Enabled
(Required for Unknown VLAN operation.)

Unknown VLAN Settings
Default: **Learn**

Figure 3-3. Example of GVRP Unknown VLAN Settings

Per-Port Options for Dynamic VLAN Advertising and Joining

Initiating Advertisements. As described in the preceding section, to enable dynamic joins, GVRP must be enabled and a port must be configured to Learn (the default). However, to send advertisements in your network, one or more static (**Tagged**, **Untagged**, or **Auto**) VLANs must be configured on one or more switches (with GVRP enabled), depending on your topology.

Enabling a Port for Dynamic Joins. You can configure a port to dynamically join a static VLAN. The join will then occur if that port subsequently receives an advertisement for the static VLAN. (This is done by using the **Auto** and **Learn** options described in table 3-2, on the next page.

Parameters for Controlling VLAN Propagation Behavior. You can configure an individual port to actively or passively participate in dynamic VLAN propagation or to ignore dynamic VLAN (GVRP) operation. These options are controlled by the GVRP “Unknown VLAN” and the static VLAN configuration parameters, as described in the following table:

Table 3-2. Controlling VLAN Behavior on Ports with Static VLANs

Per-Port “Unknown VLAN” (GVRP) Configuration	Static VLAN Options—Per VLAN Specified on Each Port ¹		
	Port Activity: Tagged or Untagged (Per VLAN) ²	Port Activity: Auto ² (Per VLAN)	Port Activity: Forbid (Per VLAN) ²
Learn (the Default)	The port: • Belongs to specified VLAN. • Advertises specified VLAN. • Can become a member of dynamic VLANs for which it receives advertisements. • Advertises dynamic VLANs that have at least one other port (on the same switch) as a member.	The port: • Will become a member of specified VLAN if it receives advertisements for specified VLAN from another device. • Will advertise specified VLAN. • Can become a member of other, dynamic VLANs for which it receives advertisements. • Will advertise a dynamic VLAN that has at least one other port (on the same switch) as a member.	The port: 1. Will not become a member of the specified VLAN. 2. Will not advertise specified VLAN. 3. Can become a member of other dynamic VLANs for which it receives advertisements. 4. Will advertise a dynamic VLAN that has at least one other port on the same switch as a member.
Block	The port: • Belongs to the specified VLAN. • Advertises this VLAN. • Will not become a member of new dynamic VLANs for which it receives advertisements. • Will advertise dynamic VLANs that have at least one other port as a member.	The port: • Will become a member of specified VLAN if it receives advertisements for this VLAN. • Will advertise this VLAN. • Will not become a member of new dynamic VLANs for which it receives advertisements. • Will advertise dynamic VLANs that have at least one other port (on the same switch) as a member.	The port: • Will not become a member of the specified VLAN. • Will not advertise this VLAN. • Will not become a member of dynamic VLANs for which it receives advertisements. • Will advertise dynamic VLANs that have at least one other port (on the same switch) as a member.
Disable	The port: • Is a member of the specified VLAN. • Will ignore GVRP PDUs. • Will not join any advertised VLANs. • Will not advertise VLANs.	The port: • Will not become a member of the specified VLAN. • Will ignore GVRP PDUs. • Will not join any dynamic VLANs. • Will not advertise VLANs.	The port: • Will not become a member of this VLAN. • Will ignore GVRP PDUs. • Will not join any dynamic VLANs. • Will not advertise VLANs.

¹ Each port of the switch must be a Tagged or Untagged member of at least one VLAN. Thus, any port configured for GVRP to Learn or Block will generate and forward advertisements for static VLAN(s) configured on the switch and also for dynamic VLANs the switch learns on other ports.

² To configure tagging, **Auto**, or **Forbid**, see “Configuring Static VLAN Per-Port Settings” on page 2-38 (for the CLI) or “Adding or Changing a VLAN Port Assignment” on page 2-26 (for the menu).

As the preceding table indicates, when you enable GVRP, a port that has a Tagged or Untagged static VLAN has the option for both generating advertisements and dynamically joining other VLANs.

Note

In table 3-2, above, the Unknown VLAN parameters are configured on a per-port basis using the CLI. The Tagged, Untagged, Auto, and Forbid options are configured per static VLAN on every port, using either the menu interface or the CLI.

Because dynamic VLANs operate as Tagged VLANs, and because a tagged port on one device cannot communicate with an untagged port on another device, ProCurve recommends that you use Tagged VLANs for the static VLANs you will use to generate advertisements.

GVRP and VLAN Access Control

Advertisements and Dynamic Joins

When you enable GVRP on a switch, the default GVRP parameter settings allow all of the switch's ports to transmit and receive dynamic VLAN advertisements (GVRP advertisements) and to dynamically join VLANs. The two preceding sections describe the per-port features you can use to control and limit VLAN propagation. To summarize, you can:

- Allow a port to advertise and/or join dynamic VLANs (Learn mode—the default).
- Allow a port to send VLAN advertisements, but not receive them from other devices; that is, the port cannot dynamically join a VLAN but other devices can dynamically join the VLANs it advertises (Block mode).
- Prevent a port from participating in GVRP operation (Disable mode).

Port-Leave From a Dynamic VLAN

A dynamic VLAN continues to exist on a port for as long as the port continues to receive advertisements of that VLAN from another device connected to that port or until you:

- Convert the VLAN to a static VLAN (See “Converting a Dynamic VLAN to a Static VLAN” on page 3-17.)
- Reconfigure the port to **Block** or **Disable**

- Disable GVRP
- Reboot the switch

The time-to-live for dynamic VLANs is 10 seconds. That is, if a port has not received an advertisement for an existing dynamic VLAN during the last 10 seconds, the port removes itself from that dynamic VLAN.

Planning for GVRP Operation

These steps outline the procedure for setting up dynamic VLANs for a segment.

1. Determine the VLAN topology you want for each segment (broadcast domain) on your network.
2. Determine the VLANs that must be static and the VLANs that can be dynamically propagated.
3. Determine the device or devices on which you must manually create static VLANs in order to propagate VLANs throughout the segment.
4. Determine security boundaries and how the individual ports in the segment will handle dynamic VLAN advertisements. (See table 3-1 on page 3-8 and table 3-2 on page 3-10.)
5. Enable GVRP on all devices you want to use with dynamic VLANs and configure the appropriate “Unknown VLAN” parameter (**Learn**, **Block**, or **Disable**) for each port.
6. Configure the static VLANs on the switch(es) where they are needed, along with the per-VLAN parameters (**Tagged**, **Untagged**, **Auto**, and **Forbid**—see table 3-2 on page 3-10) on each port.
7. Dynamic VLANs will then appear automatically, according to the configuration options you have chosen.
8. Convert dynamic VLANs to static VLANs where you want dynamic VLANs to become permanent.

Configuring GVRP On a Switch

The procedures in this section describe how to:

- View the GVRP configuration on a switch
- Enable and disable GVRP on a switch
- Specify how individual ports will handle advertisements

To view or configure static VLANs for GVRP operation, refer to “Per-Port Static VLAN Configuration Options” on page 2-13.

Menu: Viewing and Configuring GVRP

1. From the Main Menu, select:
 2. **Switch Configuration ...**
 8. **VLAN Menu ...**
 1. **VLAN Support**

Figure 3-4. The VLAN Support Screen (Default Configuration)

2. Do the following to enable GVRP and display the Unknown VLAN fields:
 - a. Press [E] (for **E**dit).
 - b. Use [↓] to move the cursor to the **GVRP Enabled** field.
 - c. Press the Space bar to select **Yes**.
 - d. Press [↓] again to display the **Unknown VLAN** fields.

GVRP

Configuring GVRP On a Switch

The Unknown VLAN

fields enable you to

configure each port to:

- Learn - Dynamically join any advertised VLAN and advertise all VLANs learned through other ports.
- Block - Do not dynamically join any VLAN, but still advertise all VLANs learned through other ports.
- Disable - Ignore and drop all incoming advertisements and do not transmit any advertisements.

```
===== CONSOLE - MANAGER MODE =====
                          Switch Configuration - VLAN - VLAN Support
Maximum VLANs to support [8] : 8
Primary VLAN : DEFAULT_VLAN
GVRP Enabled [No] : Yes

Port   Type   Unknown VLAN | Port   Type   Unknown VLAN
-----+-----+-----

Actions->  C_a_n_c_e_l    E_d_i_t    S_a_v_e    H_e_l_p

Use arrow keys to change field selection, <Space> to toggle field choices,
and <Enter> to go to Actions.
```

Figure 3-5. Example Showing Default Settings for Handling Advertisements

3. Use the arrow keys to select the port you want, and the Space bar to select Unknown VLAN option for any ports you want to change.
4. When you finish making configuration changes, press [Enter], then [S] (for **S**ave) to save your changes to the Startup-Config file.

CLI: Viewing and Configuring GVRP

GVRP Commands Used in This Section

show gvrp	below
gvrp	page 3-15
unknown-vlans	page 3-15

Displaying the Switch's Current GVRP Configuration. This command shows whether GVRP is disabled, along with the current settings for the maximum number of VLANs and the current Primary VLAN. (For more on the last two parameters, see chapter 2, "Static Virtual LANs (VLANs)".)

Syntax: show gvrp
 Shows the current settings.

```
ProCurve> show gvrp
GVRP support
  Maximum VLANs to support : 8
  Primary VLAN : DEFAULT_VLAN
  GVRP Enabled : No
```

Figure 3-6. Example of “Show GVRP” Listing with GVRP Disabled

```
ProCurve> show gvrp
GVRP support
  Maximum VLANs to support : 8
  Primary VLAN : DEFAULT_VLAN
  GVRP Enabled : Yes

  Port Type      | Unknown VLAN
  ---- +-----+
A1   10/100TX   | Learn
A2   10/100TX   | Learn
A3   10/100TX   | Block
A4   10/100TX   | Disable
A5   10/100TX   | Disable
A6   10/100TX   | Learn
A7   10/100TX   | Learn
.      .        | .
.      .        | .
.      .        | .
```

This example includes non-default settings for the Unknown VLAN field for some ports.

Figure 3-7. Example of Show GVRP Listing with GVRP Enabled

Enabling and Disabling GVRP on the Switch. This command enables GVRP on the switch.

Syntax: gvrp

This example enables GVRP:

```
ProCurve(config)# gvrp
```

This example disables GVRP operation on the switch:

```
ProCurve(config)# no gvrp
```

Enabling and Disabling GVRP On Individual Ports. When GVRP is enabled on the switch, use the **unknown-vlans** command to change the Unknown VLAN field for one or more ports. You can use this command at either the Manager level or the interface context level for the desired port(s).

Syntax: interface < port-list > unknown-vlans < learn | block | disable >

Changes the Unknown VLAN field setting for the specified port(s).

For example, to change and view the configuration for ports A1-A2 to **Block**:

```
ProCurve(config)interface a1-a2 unknown-vlans block

HP4108(config)show gvrp
GVRP support
Maximum VLANs to support : 8
Primary VLAN : DEFAULT_VLAN
GVRP Enabled : Yes

Port Type      | Unknown VLAN
----+-----
1    10/100TX  | Block
2    10/100TX  | Block
3    10/100TX  | Learn
4    10/100TX  | Learn
.          .
.          .
.          .
```

Figure 3-8. Displaying the Static and Dynamic VLANs Active on the Switch

Syntax: show vlans

*The **show vlans** command lists all VLANs present in the switch.*

For example, in the following illustration, switch “B” has one static VLAN (the default VLAN), with GVRP enabled and port 1 configured to **Learn** for Unknown VLANs. Switch “A” has GVRP enabled and has three static VLANs: the default VLAN, VLAN-222, and VLAN-333. In this scenario, switch B will dynamically join VLAN-222 and VLAN-333:

The **show vlans** command lists the dynamic (and static) VLANs in switch "B" after it has learned and joined VLAN-222 and VLAN-333.

```
Switch-B> show vlans
Status and Counters - VLAN Information

VLAN support : Yes
Maximum VLANs to support : 8
Primary VLAN : DEFAULT_VLAN

802.1Q VLAN ID Name          Status
-----
1          DEFAULT_VLAN      Static
222         GVRP_222         Dynamic
333         GVRP_333         Dynamic
```

Dynamic VLANs Learned from Switch "A" through Port 1

Figure 3-9. Example of Listing Showing Dynamic VLANs

Converting a Dynamic VLAN to a Static VLAN. If a port on the switch has joined a dynamic VLAN, you can use the following command to convert that dynamic VLAN to a static VLAN:

Syntax: static < dynamic-vlan-id >

Converts the a dynamic VLAN to a static VLAN.

For example, to convert dynamic VLAN 333 (from the previous example) to a static VLAN:

```
ProCurve(config)# static 333
```

When you convert a dynamic VLAN to a static VLAN, all ports on the switch are assigned to the VLAN in Auto mode.

Web: Viewing and Configuring GVRP

To view, enable, disable, or reconfigure GVRP:

1. Click on the **Configuration** tab.
2. Click on **[VLAN Configuration]** and do the following:
 - To enable or disable GVRP, click on **GVRP Enabled**.
 - To change the Unknown VLAN field for any port:
 - i. Click on **[GVRP Security]** and make the desired changes.
 - ii. Click on **[Apply]** to save and implement your changes to the Unknown VLAN fields.

For web-based Help on how to use the web browser interface screen, click on the **[?]** button provided on the web browser screen.

GVRP Operating Notes

- A dynamic VLAN must be converted to a static VLAN before it can have an IP address.
- On the switches covered in this guide, GVRP can be enabled only if **max vlans** is set to no more than 256 VLANs.
- The total number of VLANs on the switch (static and dynamic combined) cannot exceed the current Maximum VLANs setting. For example, in the factory default state, the switch supports eight VLANs. Thus, in a case where four static VLANs are configured on the switch, the switch can accept up to four additional VLANs in any combination of static and dynamic. Any additional VLANs advertised to the switch will not be added unless you first increase the Maximum VLANs setting. In the Menu interface, click on **2. Switch Configuration ... | 8. VLAN Menu | 1. VLAN Support**. In the global config level of the CLI, use **max-vlans**.
- Converting a dynamic VLAN to a static VLAN and then executing the **write memory** command saves the VLAN in the startup-config file and makes it a permanent part of the switch's VLAN configuration.
- Within the same broadcast domain, a dynamic VLAN can pass through a device that is not GVRP-aware. This is because a hub or a switch that is not GVRP-aware will flood the GVRP (multicast) advertisement packets out all ports.
- GVRP assigns dynamic VLANs as Tagged VLANs. To configure the VLAN as Untagged, you must first convert it to a static VLAN.

- Rebooting a switch on which a dynamic VLAN exists deletes that VLAN. However, the dynamic VLAN re-appears after the reboot if GVRP is enabled and the switch again receives advertisements for that VLAN through a port configured to add dynamic VLANs.
- By receiving advertisements from other devices running GVRP, the switch learns of static VLANs on those other devices and dynamically (automatically) creates tagged VLANs on the links to the advertising devices. Similarly, the switch advertises its static VLANs to other GVRP-aware devices, as well as the dynamic VLANs the switch has learned.
- A GVRP-enabled switch does not advertise any GVRP-learned VLANs out of the port(s) on which it originally learned of those VLANs.
- A VLAN enabled for jumbo traffic cannot be used to create a dynamic VLAN. A port belonging to a statically configured, jumbo-enabled VLAN cannot join a dynamic VLAN.

Without spanning tree, having more than one active path between a pair of nodes causes loops in the network, which can result in duplication of messages, leading to a “broadcast storm” that can bring down the network.

Multiple-Instance spanning tree operation (802.1s) ensures that only one active path exists between any two nodes in a spanning-tree *instance*. A spanning-tree instance comprises a unique set of VLANs, and belongs to a specific spanning-tree *region*. A region can comprise multiple spanning-tree instances (each with a different set of VLANs), and allows one active path among regions in a network. Applying VLAN tagging to the ports in a multiple-instance spanning-tree network enables blocking of redundant links in one instance while allowing forwarding over the same links for non-redundant use by another instance.

For example, suppose you have three switches in a region configured with VLANs grouped into two instances, as follows:

VLANs	Instance 1	Instance 2
10, 11, 12	Yes	No
20, 21, 22	No	Yes

The logical and physical topologies resulting from these VLAN/Instance groupings result in blocking on different links for different VLANs:

Figure 4-1. Example of a Multiple Spanning-Tree Application

802.1s Multiple Spanning Tree Protocol (MSTP)

The 802.1D and 802.1w spanning tree protocols operate without regard to a network's VLAN configuration, and maintain one common spanning tree throughout a bridged network. Thus, these protocols map one loop-free, logical topology on a given physical topology. The 802.1s Multiple Spanning Tree protocol (MSTP) uses VLANs to create multiple spanning trees in a network, which significantly improves network resource utilization while maintaining a loop-free environment.

While the per-VLAN spanning tree approach adopted by some vendors overcomes the network utilization problems inherent in using STP or RSTP, using a per-VLAN technology with multiple VLANs can overload the switch's CPU. MSTP on the switches covered in this guide complies with the IEEE 802.1s standard, and extends STP and RSTP functionality to map multiple independent spanning tree instances onto a physical topology. With MSTP, each spanning tree instance can include one or more VLANs and applies a separate, per-instance forwarding topology. Thus, where a port belongs to multiple VLANs, it may be dynamically blocked in one spanning tree instance, but forwarding in another instance. This achieves load-balancing across the network while keeping the switch's CPU load at a moderate level (by aggregating multiple VLANs in a single spanning tree instance). MSTP provides fault tolerance through rapid, automatic reconfiguration if there is a failure in a network's physical topology.

With MSTP-capable switches, you can create a number of MST regions containing multiple spanning tree instances. This requires the configuration of a number of MSTP-capable switches. However, it is NOT necessary to do this. You can just enable MSTP on an MSTP-capable switch and a spanning tree instance is created automatically. This instance always exists by default when spanning tree is enabled, and is the spanning tree instance that communicates with STP and RSTP environments. The MSTP configuration commands operate exactly like RSTP commands and MSTP is backward-compatible with the RSTP-enabled and STP-enabled switches in your network.

Caution

Spanning tree interprets a switch mesh as a single link. Because the switch automatically gives faster links a higher priority, the default MSTP parameter settings are usually adequate for spanning tree operation. Also, because incorrect MSTP settings can adversely affect network performance, you should not change the MSTP settings from their default values unless you have a strong understanding of how spanning tree operates.

In a mesh environment, the default MSTP timer settings (**Hello Time** and **Forward Delay**) are usually adequate for MSTP operation. Because a packet crossing a mesh may traverse several links within the mesh, using smaller-than-default settings for the MSTP **Hello Time** and **Forward Delay** timers can cause unnecessary topology changes and end-node connectivity problems.

For MSTP information beyond what is provided in this manual, refer to the IEEE 802.1s standard.

MSTP Structure

MSTP maps active, separate paths through separate spanning tree instances and between MST regions. Each MST region comprises one or more MSTP switches. Note that MSTP recognizes an STP or RSTP LAN as a distinct spanning-tree region.

Figure 4-2. Example of MSTP Network with Legacy STP and RSTP Devices Connected

Common and Internal Spanning Tree (CIST): The CIST identifies the regions in a network and administers the CIST root bridge for the network, the root bridge for each region, and the root bridge for each spanning-tree instance in each region.

Common Spanning Tree (CST): The CST administers the connectivity among the MST regions, STP LANs, and RSTP LANs in a bridged network.

MST Region: An MST region comprises the VLANs configured on physically connected MSTP switches. All switches in a given region must be configured with the same VLANs, the same Multiple Spanning Tree Instances (MSTIs), and the same MST configuration identifiers.

Internal Spanning Tree (IST): The IST administers the topology within a given MST region. When you configure a switch for MSTP operation, the switch automatically includes all of the static VLANs configured on the switch in a single, active spanning tree topology (instance) within the IST. This is termed the “IST instance”. Any VLANs you subsequently configure on the switch are added to this IST instance. To create separate forwarding paths within a region, group specific VLANs into different Multiple Spanning Tree Instances (MSTIs). (Refer to “Multiple Spanning Tree Instance (MSTI)”, below.)

Types of Multiple Spanning Tree Instances: A multiple spanning tree network comprises separate spanning-tree instances existing in an MST region. (There can be multiple regions in a network.) Each instance defines a single forwarding topology for an exclusive set of VLANs. By contrast, an STP or RSTP network has only one spanning tree instance for the entire network, and includes all VLANs in the network. (An STP or RSTP network operates as a single-instance network.) A region can include two types of STP instances:

- **Internal Spanning-Tree Instance (IST Instance):** This is the default spanning tree instance in any MST region. It provides the root switch for the region and comprises all VLANs configured on the switches in the region that are not specifically assigned to Multiple Spanning Tree Instances (MSTIs, described below).

Within a region, the IST instance provides a loop-free forwarding path for all VLANs associated with it. VLANs that are not associated with an MSTI are, by default, associated with the IST instance. Note that the switch automatically places dynamic VLANs (resulting from GVRP operation) in the IST instance. Dynamic VLANs cannot exist in an MSTI (described below).

- **Multiple Spanning Tree Instance (MSTI):** This type of configurable spanning tree instance comprises all static VLANs you specifically assign to it, and must include at least one VLAN. The VLAN(s) you assign to an

MSTI must initially exist in the IST instance of the same MST region. When you assign a static VLAN to an MSTI, the switch removes the VLAN from the IST instance. (Thus, you can assign a VLAN to only one MSTI in a given region.) All VLANs in an MSTI operate as part of the same single spanning tree topology. (The switch does not allow dynamic VLANs in an MSTI.)

Caution

When you enable MSTP on the switch, the default MSTP spanning tree configuration settings comply with the values recommended in the IEEE 802.1s Multiple Spanning Tree Protocol (MSTP) standard. Note that inappropriate changes to these settings can result in severely degraded network performance. For this reason, *ProCurve strongly recommends that changing these default settings be reserved only for experienced network administrators who have a strong understanding of the IEEE 802.1D/w/s standards and operation.*

How MSTP Operates

In the factory default configuration, spanning tree operation is off. Also, the switch retains its currently configured spanning tree parameter settings when disabled. Thus, if you disable spanning tree, then later re-enable it, the parameter settings will be the same as before spanning tree was disabled. The switch also includes a “Pending” feature that enables you to exchange MSTP configurations with a single command. (Refer to “Enabling an Entire MST Region at Once or Exchanging One Region Configuration for Another” on page 4-45.)

Note

The switch automatically senses port identity and type, and automatically defines spanning-tree parameters for each type, as well as parameters that apply across the switch. Although these parameters can be adjusted, *ProCurve strongly recommends leaving these settings in their default configurations unless the proposed changes have been supplied by an experienced network administrator who has a strong understanding of the IEEE 802.1D/w/s standards and operation.*

MST Regions

All MSTP switches in a given region must be configured with the same VLANs. Also, each MSTP switch within the same region must have the same VLAN-to-instance assignments. (A VLAN can belong to only one instance within any region.) Within a region:

- All of the VLANs belonging to a given instance compose a single, active spanning-tree topology for that instance.
- Each instance operates independently of other regions.

Between regions there is a single, active spanning-tree topology.

How Separate Instances Affect MSTP Operation. Assigning different groups of VLANs to different instances ensures that those VLAN groups use independent forwarding paths. For example, in figure 4-3 each instance has a different forwarding path.

Figure 4-3. Active Topologies Built by Three Independent MST Instances

While allowing only one active path through a given instance, MSTP retains any redundant physical paths in the instance to serve as backups (blocked) paths in case the existing active path fails. Thus, if an active path in an instance fails, MSTP automatically activates (unblocks) an available backup to serve as the new active path through the instance for as long as the original active path is down. Note also that a given port may simultaneously operate in different states (forwarding or blocking) for different spanning-tree instances within the same region. This depends on the VLAN memberships to which the port is assigned. For example, if a port belongs to VLAN 1 in the IST instance of a region and also belongs to VLAN 4 in MSTI "x" in the same region, the port may apply different states to traffic for these two different instances.

Within a region, traffic routed between VLANs in separate instances can take only one physical path. To ensure that traffic in all VLANs within a region can travel between regions, all of the boundary ports for each region should belong to all VLANs configured in the region. Otherwise, traffic from some areas within a region could be blocked from moving to other regions.

All MSTP switches (as well as STP and RSTP switches) in a network use BPDUs (Bridge Protocol Data Units) to exchange information from which to build multiple, active topologies in the individual instances within a region and between regions. From this information:

- The MSTP switches in each LAN segment determine a designated bridge and designated port or trunk for the segment.
- The MSTP switches belonging to a particular instance determine the root bridge and root port or trunk for the instance.
- For the IST instance within a region, the MSTP switches linking that region to other regions (or to STP or RSTP switches) determine the IST root bridge and IST root port or trunk for the region. (For any Multiple Spanning-Tree instance—MSTI—in a region, the regional root may be a different switch that is not necessarily connected to another region.)
- The MSTP switches block redundant links within each LAN segment, across all instances, and between regions, to prevent any traffic loops.

As a result, each individual instance (spanning tree) within a region determines its regional root bridge, designated bridges, and designated ports or trunks.

Regions, Legacy STP and RSTP Switches, and the Common Spanning Tree (CST)

The IST instance and any MST instances in a region exist only within that region. Where a link crosses a boundary between regions (or between a region and a legacy STP or RSTP switch), traffic is forwarded or blocked as determined by the Common Spanning Tree (CST). The CST ensures that there is only one active path between any two regions, or between a region and a switch running STP and RSTP. (Refer to figure 4-2 on page 4-7.)

MSTP Operation with 802.1Q VLANs

As indicated in the preceding sections, within a given MST instance, a single spanning tree is configured for all VLANs included in that instance. This means that if redundant physical links exist in separate VLANs within the same instance, MSTP blocks all but one of those links. However, you can prevent the bandwidth loss caused by blocked redundant links for different VLANs in

an instance by using a port trunk. The following example shows how you can use a port trunk with 802.1Q (tagged) VLANs and MSTP without unnecessarily blocking any links or losing any bandwidth.

Figure 4-4. Example of Using a Trunked Link To Support Multiple VLAN Connectivity within the Same MST Instance

Note

All switches in a region should be configured with the VLANs used in that region, and all ports linking MSTP switches together should be members of all VLANs in the region. Otherwise, the path to the root for a given VLAN will be broken if MSTP selects a spanning tree through a link that does not include that VLAN.

Terminology

BPDU — Acronym for bridge protocol data unit. BPDUs are data messages that are exchanged between the switches within an extended LAN that use a spanning tree protocol topology. BPDU packets contain information on ports, addresses, priorities and costs and ensure that the data ends up where it was

intended to go. BPDU messages are exchanged across bridges to detect loops in a network topology. The loops are then removed by placing redundant switch ports in a backup, or blocked, state.

BPDU Filtering — Spanning-tree configuration mode that prevents the switch from receiving and transmitting BPDU frames on a specific port (see page 4-29 for details).

BPDU Protection — Spanning-tree configuration mode which disables a port where BPDU frames are received (see page 4-30 for details).

Bridge: See “MSTP Bridge”.

Common and Internal Spanning Tree (CIST): Comprises all LANs, STP, and RSTP bridges and MSTP regions in a network. The CIST automatically determines the MST regions in a network and defines the root bridge (switch) and designated port for each region. The CIST includes the Common Spanning Tree (CST), the Internal Spanning Tree (IST) within each region, and any multiple spanning-tree instances (MSTIs) in a region.

Common Spanning Tree (CST): Refers to the single forwarding path the switch calculates for STP (802.1D) and RSTP (802.1w) topologies, and for inter-regional paths in MSTP (802.1s) topologies. Note that all three types of spanning tree can interoperate in the same network. Also, the MSTP switch interprets a device running 802.1D STP or 802.1w RSTP as a separate region. (Refer to figure 4-2 on page 4-7.)

Internal Spanning Tree (IST): Comprises all VLANs within a region that are not assigned to a multiple spanning-tree instance configured within the region. All MST switches in a region should belong to the IST. In a given region “X”, the IST root switch is the regional root switch and provides information on region “X” to other regions.

MSTP (Multiple Spanning Tree Protocol): A network supporting MSTP allows multiple spanning tree instances within configured regions, and a single spanning tree among regions, STP bridges, and RSTP bridges.

MSTP BPDU (MSTP Bridge Protocol Data Unit): These BPDUs carry region-specific information, such as the region identifier (region name and revision number). If a switch receives an MSTP BPDU with a region identifier that differs from its own, then the port on which that BPDU was received is on the boundary of the region in which the switch resides.

MSTP Bridge: In this manual, an MSTP bridge is a switch (or another 802.1s-compatible device) configured for MSTP operation.

MST Region: An MST region forms a multiple spanning tree domain and is a component of a single spanning-tree domain within a network. For switches internal to the MST region:

- All switches have identical MST configuration identifiers (region name and revision number).
- All switches have identical VLAN assignments to the region's IST and (optional) MST instances.
- One switch functions as the designated bridge (IST root) for the region.
- No switch has a point-to-point connection to a bridging device that cannot process RSTP BPDUs.

RSTP — Rapid Spanning Tree Protocol, defined in IEEE 802.1w and ratified in IEEE 802.1D-2004.

Spanning-tree — Generic term to refer to the many spanning-tree flavors: now deprecated STP, RSTP and VLAN-aware MSTP.

STP — Spanning Tree Protocol, part of the original IEEE 802.1D specification. The 2004 edition completely deprecates STP. Both RSTP and MSTP have fallback modes to handle STP.

SNMP — Simple Network Management Protocol, used to remotely manage network devices.

Operating Rules

- All switches in a region must be configured with the same set of VLANs, as well as the same MST configuration name and MST configuration number.
- Within a region, a VLAN can be allocated to either a single MSTI or to the region's IST instance.
- All switches in a region must have the same VID-to-MST instance assignment.
- There is one root MST switch per configured MST instance.
- Because boundary ports provide the VLAN connectivity between regions, all boundary ports on a region's root switch should be configured as members of all static VLANs defined in the region.
- There is one root switch for the Common and Internal Spanning Tree (CIST). At any given time, all switches in the network will use the per-port **hello-time** parameter assignments configured on the CIST root switch.

- Where multiple MST regions exist in a network, there is only one active, physical communication path between any two regions, or between an MST region and an STP or RSTP switch. MSTP blocks any other physical paths as long as the currently active path remains in service.
- Within a network, an MST region appears as a virtual RSTP bridge to other spanning tree entities (other MST regions, and any switches running 802.1D or 802.1w spanning-tree protocols).
- Within an MSTI, there is one physical communication path between any two nodes, regardless of how many VLANs belong to the MSTI. Within an IST instance, there is also one spanning tree across all VLANs belonging to the IST instance.
- An MSTI comprises a unique set of VLANs and forms a single spanning-tree instance within the region to which it belongs.
- A dynamic VLAN learned by GVRP will always be placed in the IST instance and cannot be moved to any configured MST instance.

Starting in software release 13.x.x, dynamically learned GVRP VLANs can be mapped to MSTIs and support MSTP load balancing.

- In software release 13.x.x and later, you can preconfigure static and dynamic VLAN ID-to-MSTI mappings before the VLAN is created on the switch. Later, when the static VLAN ID is configured or a dynamic GVRP VLAN is learned, the VLAN is automatically associated with the preconfigured MSTI. For more information, refer to the **spanning-tree instance vlan** command description on page 4-41.
- Communication between MST regions uses a single spanning tree.
- If a port on a switch configured for MSTP receives a legacy (STP/802.1D or RSTP/802.1w) BPDU, it automatically operates as a legacy port. In this case, the MSTP switch interoperates with the connected STP or RSTP switch as a separate MST region.
- Within an MST region, there is one logical forwarding topology per instance, and each instance comprises a unique set of VLANs. Where multiple paths exist between a pair of nodes using VLANs belonging to the same instance, all but one of those paths will be blocked for that instance. However, if there are different paths in different instances, all such paths are available for traffic. Separate forwarding paths exist through separate spanning tree instances.
- A port can have different states (forwarding or blocking) for different instances (which represent different forwarding paths).
- MSTP interprets a switch mesh as a single link.

MSTP Compatibility with RSTP or STP

IEEE 802.1s MSTP includes RSTP functionality and is designed to be compatible with both IEEE 802.1D and 802.1w spanning-tree protocols. Using the default configuration values, your switches will interoperate effectively with RSTP and STP devices. MSTP automatically detects when the switch ports are connected to non-MSTP devices in the spanning tree and communicates with those devices using 802.1D or 802.1w STP BPDU packets, as appropriate.

To enable effective interoperation with STP (802.1D) configured devices, however, you may need to adjust the default configuration values. Here are two such examples:

- The rapid state transitions employed by MSTP may result in an increase in the rates of frame duplication and misordering in the switched LAN. To allow the switch to support applications and protocols that may be sensitive to frame duplication and misordering, you can disable rapid transitions by setting the Force Protocol Version parameter to **STP-compatible**. The value of this parameter applies to all ports on the switch. See information on **force version** on page 4-21.
- One of the benefits of MSTP is the implementation of a larger range of port path costs, which accommodates higher network speeds. However, this can create some incompatibility between devices running the older 802.1D STP. You can adjust to this incompatibility by implementing the global **spanning-tree legacy-path cost** command (see page 4-22). See also the “Note on Path Cost” below.

Note on Path Cost

RSTP and MSTP implement a greater range of path costs than 802.1D STP, and use different default path cost values to account for higher network speeds. These values are shown below.

Port Type	802.1D STP Path Cost	RSTP and MSTP Path Cost
10 Mbps	100	2 000 000
100 Mbps	10	200 000
1 Gbps	5	20 000

Because the maximum value for the path cost allowed by 802.1D STP is 65535, devices running that version of spanning tree cannot be configured to match the values defined by MSTP, at least for 10 Mbps and 100 Mbps ports. In LANs where there is a mix of devices running 802.1D STP, RSTP, and/or MSTP, you should reconfigure the devices so the path costs match for ports with the same network speeds.

Configuring MSTP

This section outlines the main pre-requisites for configuring MSTP in your network, and describes MSTP settings at the global level, per individual port, and per MST instance.

Planning an MSTP Application

Before configuring MSTP, keep in mind the following tips and considerations:

- Ensure that the VLAN configuration in your network supports all of the forwarding paths necessary for the desired connectivity. All ports connecting one switch to another within a region and one switch to another between regions should be configured as members of all VLANs configured in the region.
- Configure all ports or trunks connecting one switch to another within a region as members of all VLANs in the region. Otherwise, some VLANs could be blocked from access to the spanning-tree root for an instance or for the region.
- Plan individual regions based on VLAN groupings. That is, plan on all MSTP switches in a given region supporting the same set of VLANs. Within each region, determine the VLAN membership for each spanning-tree instance. (Each instance represents a single forwarding path for all VLANs in that instance.)
- Verify that there is one logical spanning-tree path through the following:
 - Any inter-regional links
 - Any IST or MST instance within a region
 - Any legacy (802.1D or 802.1w) switch or group of switches. (Where multiple paths exist between an MST region and a legacy switch, expect the CST to block all but one such path.)
- Determine the root bridge and root port for each instance.
- Determine the designated bridge and designated port for each LAN segment.
- Determine which VLANs to assign to each instance, and use port trunks with 802.1Q VLAN tagging where separate links for separate VLANs would result in a blocked link preventing communication between nodes on the same VLAN. (Refer to “MSTP Operation with 802.1Q VLANs” on page 4-11.)

- Identify the edge ports connected to end nodes and enable the admin-edge-port setting for these ports. Leave the admin-edge-port setting disabled for ports connected to another switch, a bridge, or a hub.

Note on MSTP Rapid State Transitions

Under some circumstances the rapid state transitions employed by MSTP can increase the rates of frame duplication and misordering in the switched LAN. To allow MSTP switches to support applications and protocols that may be sensitive to frame duplication and misordering, setting the Force Protocol Version (**force-version**) parameter to **stp-compatible** allows MSTP to operate with rapid transitions disabled. The value of this parameter applies to all ports on the switch. See the information on **force-version** on page 4-21.

MSTP Configuration Overview

This section outlines the general steps for configuring MSTP via the CLI, assuming that you have already determined the VLANs you want MSTP to use (see “Planning an MSTP Application” on page 4-17). Detailed descriptions of the MSTP commands and parameters referenced below are provided in the following sections.

1. Configure MSTP global parameters.

This step involves configuring the following:

- Required parameters for MST region identity:
 - Region Name: **spanning-tree config-name**
 - Region Revision Number: **spanning-tree config-revision**

- Optional MSTP parameter changes for region settings:

ProCurve recommends that you leave these parameters at their default settings for most networks. See the “Caution” on page 4-9.

- The maximum number of hops before the MSTP BPDU is discarded: **spanning-tree max-hops** (default: 20)
- Force-Version operation: **spanning-tree force-version**
- Forward Delay: **spanning-tree forward-delay**
- Hello Time (if it is the root device): **spanning-tree hello-time**
- Maximum age to allow for STP packets before discarding: **spanning-tree maximum-age**

- Device spanning-tree priority. Specifies the priority value used along with the switch MAC address to determine which device is root. The lower a priority value, the higher the priority.

spanning-tree priority

2. Configure per port parameters.

ProCurve recommends that you use the default settings for these parameters and apply changes on a per-port basis only where a non-default setting is clearly indicated by the circumstances of individual links. Other features you might consider include BPDU Filtering or BPDU Protection—these provide additional per-port control over spanning-tree operations and security on the switch.

3. Configure MST instances.

- Configure one instance for each VLAN group that you want to operate as an active topology within the region to which the switch belongs. When you create the instance, you must include a minimum of one VID. You can add more VIDs later if desired.

spanning-tree instance < n > **vlan** < vid >

To move a VLAN from one instance to another, first use **no spanning-tree instance** < n > **vlan** < vid > to unmap the VLAN from the current instance, then add the VLAN to the other instance. (While the VLAN is unmapped from an MSTI, it is associated with the region's IST instance.)

4. Configure the priority for each instance.

spanning-tree instance < n > **priority** < n >

5. Configure MST instance port parameters.

ProCurve recommends that you apply changes on a per-port basis only where a non-default setting is clearly indicated by the circumstances of individual links. For example, you might want to set the path cost value for the port(s) used by a specific MST instance.

spanning-tree instance < 1..16 > < port-list > **path-cost** < auto | 1..200000000 >

Alternatively, leaving this setting at the default (auto) allows the switch to calculate the path-cost from the link speed.

6. Enable spanning-tree operation on the switch.

spanning-tree

Configuring MSTP Operation Mode and Global Settings

The commands in this section apply at the switch (global) level. For details of how to configure spanning tree settings on individual ports, see “Configuring MSTP Per-Port Parameters” on page 4-25.

MSTP Global Command	Page
spanning-tree	*
config-name < <i>ascii-string</i> >	4-20
config-revision < <i>revision-number</i> >	4-21
force-version < stp-compatible rstp-operation mstp-operation >	4-21
forward-delay	4-22
hello-time < 1..10 >	4-22
legacy-mode	4-22
legacy-path-cost	4-22
max-hops < <i>hop-count</i> >	4-22
maximum-age	4-22
pending	4-23
priority	4-24
trap errant-bpdu	4-24

** Enabling MSTP operation using the **spanning-tree** global command is the final step in the configuration process. See “Enabling or Disabling Spanning Tree Operation” on page 4-45.*

Syntax: [no] spanning-tree config-name < *ascii-string* >

*This command resets the configuration name of the MST region in which the switch resides. This name can include up to 32 nonblank characters and is case-sensitive. On all switches within a given MST region, the configuration names must be identical. Thus, if you want more than one MSTP switch in the same MST region, you must configure the identical region name on all such switches. If you retain the default configuration name on a switch, it cannot exist in the same MST region with another switch.
(Default Name: A text string using the hexadecimal representation of the switch’s MAC address)*

*The **no** form of the command overwrites the currently configured name with the default name.*

Note: *This option is available only when the switch is configured for MSTP operation. Also, there is no defined limit on the number of regions you can configure.*

Syntax: spanning-tree config-revision < revision-number >

This command configures the revision number you designate for the MST region in which you want the switch to reside. This setting must be the same for all switches residing in the same region. Use this setting to differentiate between region configurations in situations such as the following:

- *Changing configuration settings within a region where you want to track the configuration versions you use*
- *Creating a new region from a subset of switches in a current region and want to maintain the same region name.*
- *Using the **pending** option to maintain two different configuration options for the same physical region.*

Note that this setting must be the same for all MSTP switches in the same MST region. (Range: 0 - 65535; Default: 0)

Note: *This option is available only when the switch is configured for MSTP operation.*

Syntax: spanning-tree force-version < stp-compatible | rstp-operation | mstp-operation >

Sets the spanning-tree compatibility mode. This command forces the switch to emulate behavior of earlier versions of spanning tree protocol, or return to MSTP behavior. The command is useful in test or debug applications, and removes the need to reconfigure the switch for temporary changes in spanning-tree operation.

stp-compatible: *The switch applies 802.1D STP operation on all ports.*

rstp-operation: *The switch applies 802.1w operation on all ports except those ports where it detects a system using 802.1D Spanning Tree.*

mstp-operation: *The switch applies 802.1s MSTP operation on all ports where compatibility with 802.1D or 802.1w spanning tree protocols is not required.*

*Note that even when mstp-operation is selected, if the switch detects an 802.1D BPDU or an 802.1w BPDU on a port, it communicates with the device linked to that port using STP or RSTP BPDU packets. Also, if errors are encountered as described in the “Note on MSTP Rapid State Transitions” on page 4-18, setting **force-version** to **stp-compatible** forces the MSTP switch to communicate out all ports using operations that are compatible with IEEE 802.1D STP.*

Syntax: spanning-tree forward-delay

Sets time the switch waits between transitioning from listening to learning and from learning to forwarding states. (Range: 4 - 30; Default: 15.)

Syntax: spanning-tree legacy-mode

Sets spanning-tree protocol to operate in 802.1D legacy mode (STP-compatible).

*(Default: **MSTP-operation.**)*

*The **no** form of the command returns the switch to the default 802.1s native mode (MSTP-operation).*

Syntax: spanning-tree legacy-path-cost

Sets spanning-tree to operate with 802.1d (legacy) path cost values.

*(Default: **802.1t.**)*

*The **no** form of the command returns the switch to the default 802.1t (not legacy) path cost values.*

Syntax: spanning-tree hello-time < 1..10 >

*If MSTP is running and the switch is operating as the CIST root for your network, this command specifies the time in seconds between transmissions of BPDUs for all ports on the switch configured with the **Global** option. (the default). This parameter applies in MSTP, RSTP and STP modes. During MSTP operation, you can override this global setting on a per-port basis with this command: **spanning-tree < port-list > hello-time < 1..10 >** (see page 4-27). (Default: **2.**)*

Syntax: spanning-tree max-hops < hop-count >

This command resets the number of hops allowed for BPDUs in an MST region. When an MSTP switch receives a BPDU, it decrements the hop-count setting the BPDU carries. If the hop-count reaches zero, the receiving switch drops the BPDU. Note that the switch does not change the message-age and maximum-age data carried in the BPDU as it moves through the MST region and is propagated to other regions. (Range: 1 - 40; Default: 20)

Syntax: spanning-tree maximum age

Sets the maximum age of received STP information before it is discarded.

*(Default: **20.**)*

Syntax: spanning-tree pending < apply | config-name | config-revision | instance | reset >

Manipulates the pending MSTP configuration. The command is useful in test or debug applications, and enables rapid reconfiguration of the switch for changes in spanning-tree operation.

apply: Apply pending MSTP configuration (swaps active and pending configurations).

config-name: Sets the pending MST region configuration name (default is switch's MAC address).

config-revision: Sets the pending MST region configuration revision number (default is 0).

instance: Change pending MST instance configuration.

reset: Copy active configuration to pending.

Syntax: spanning-tree priority < priority-multiplier >

Every switch running an instance of MSTP has a Bridge Identifier, which is a unique identifier that helps distinguish this switch from all others. The switch with the lowest Bridge Identifier is elected as the root for the tree.

The Bridge Identifier is composed of a configurable Priority component (2 bytes) and the bridge's MAC address (6 bytes). The ability to change the Priority component provides flexibility in determining which switch will be the root for the tree, regardless of its MAC address.

This command sets the switch (bridge) priority for the designated region in which the switch resides. The switch compares this priority with the priorities of other switches in the same region to determine the root switch for the region. The lower the priority value, the higher the priority. (If there is only one switch in the region, then that switch is the root switch for the region.) The root bridge in a region provides the path to connected regions for the traffic in VLANs assigned to the region's IST instance. (Traffic in VLANs assigned to a numbered STP instance in a given region moves to other regions through the root switch for that instance.)

The priority range for an MSTP switch is 0-61440. However, this command specifies the priority as a multiplier (0 - 15) of 4096. That is, when you specify a priority multiplier value of 0 - 15, the actual priority assigned to the switch is:

$$(\text{priority-multiplier}) \times 4096$$

*For example, if you configure "2" as the priority-multiplier on a given MSTP switch, then the **Switch Priority** setting is 8,192.*

Note: *If multiple switches in the same MST region have the same priority setting, then the switch with the lowest MAC address becomes the root switch for that region.*

Syntax: spanning-tree trap errant-bpdu

Enables SNMP traps for errant-BPDUs. Note that this command is designed to be used in conjunction with the spanning-tree bpdu-filter command (see page 4-29) and bpdu-protection command (see page 4-30).

*The **no** form of the command disables traps on the switch. (Default: **Disabled**.)*

Configuring MSTP Per-Port Parameters

In an MSTP topology, you configure per-port parameters in the global configuration context.

In most cases, ProCurve recommends that you use the default settings for these parameters and apply changes on a per-port basis only where a non-default setting is clearly indicated by the circumstances of individual links. Some port parameters (such as **admin-edge-port**) affect all MSTI instances that consist of VLANs configured on the port; other port parameters (such as **path-cost**) affect only the specified MST.

Per Port Command	Page
spanning-tree < port-list >	
admin-edge-port	below
auto-edge-port	4-26
bpdu-filter	4-29
bpdu-protection	4-31
mcheck	4-26
hello-time < global 1..10 >	4-27
path-cost < auto 200000000 >	4-41
point-to-point-mac < force-true force-false auto>	4-24
priority <priority-multiplier>	4-24
root-guard	4-28

pvst-filter	4-35
loop-protection	4-37

Configuring Per Port Parameters

Syntax: [no] spanning-tree <port-list> admin-edge-port

*Enable **admin-edge-port** on ports connected to end nodes. During spanning tree establishment, ports with **admin-edge-port** enabled transition immediately to the forwarding state. If a bridge or switch is detected on the segment, the port automatically operates as non-edge, not enabled. (Default: **No** - disabled)*

*If **admin-edge-port** is disabled on a port and **auto-edge-port** has not been disabled, the **auto-edge-port** setting controls the behavior of the port.*

*The **no spanning-tree < port-list > admin-edge-port** command disables edge-port operation on the specified ports.*

Syntax: [no] spanning-tree < port-list > auto-edge-port

*Supports the automatic identification of edge ports. The port will look for BPDUs for 3 seconds; if there are none it begins forwarding packets. If **admin-edge-port** is enabled for a port, the setting for **auto-edge-port** is ignored whether set to yes or no. If **admin-edge-port** is set to **No**, and **auto-edge-port** has not been disabled (set to **No**), then the **auto-edge-port** setting controls the behavior of the port. (Default: **Yes** - enabled)*

*The **no spanning-tree < port-list > auto-edge-port** command disables **auto-edge-port** operation on the specified ports.*

Syntax: spanning-tree < port-list > mcheck

Forces a port to send RST/MST BPDUs for 3 seconds. This tests whether all STP bridges on the attached LAN have been removed and the port can migrate to native MSTP mode and use RST/MST BPDUs for transmission.

Syntax: spanning-tree < port-list > hello-time < global | 1 - 10 >

*When the switch is the CIST root, this parameter specifies the interval (in seconds) between periodic BPDU transmissions by the designated ports. This interval also applies to all ports in all switches downstream from each port in the < port-list >. A setting of **global** indicates that the ports in < port-list > on the CIST root are using the value set by the global spanning-tree **hello-time** value (page 4-22). When a given switch “X” is not the CIST root, the per-port **hello-time** for all active ports on switch “X” is propagated from the CIST root, and is the same as the **hello-time** in use on the CIST root port in the currently active path from switch “X” to the CIST root. (That is, when switch “X” is not the CIST root, then the upstream CIST root’s port **hello-time** setting overrides the **hello-time** setting configured on switch “X”).*

*(Default Per-Port setting: **Use Global**.)*

*(Default Global Hello-Time: **2**.)*

Syntax: spanning-tree < port-list > path-cost < auto | 1..200000000 >

*Assigns an individual port cost that the switch uses to determine which ports are forwarding ports in a given spanning tree. In the default configuration (**auto**) the switch determines a port’s path cost by the port’s type:*

- 10 Mbps: **2000000***
- 100 Mbps: **200000***
- 1 Gbps: **20000***

Refer to “Note on Path Cost” on page 4-16 for information on compatibility with devices running 802.1D STP for the path cost values

*(Default: **Auto**).*

Syntax: spanning-tree < port-list > point-to-point-mac < force-true | force-false | auto >

This parameter informs the switch of the type of device to which a specific port connects.

Force-True (default): Indicates a point-to-point link to a device such as a switch, bridge, or end-node.

Force-False: Indicates a connection to a hub (which is a shared LAN segment).

Auto: Causes the switch to set Force-False on the port if it is not running at full duplex. (Connections to hubs are half-duplex.)

Syntax: spanning-tree < port-list > priority < priority-multiplier >

MSTP uses this parameter to determine the port(s) to use for forwarding. The port with the lowest priority number has the highest priority for use. The range is 0 to 240, and is configured by specifying a multiplier from 0 - 15. When you specify a priority multiplier of 0 - 15, the actual priority assigned to the switch is:

$$(priority-multiplier) \times 16$$

*For example, if you configure “2” as the priority multiplier on a given port, then the actual **Priority** setting is 32. Thus, after you specify the port priority multiplier, the switch displays the actual port priority (and not the multiplier) in the **show spanning-tree** or **show spanning-tree < port-list >** displays.*

*You can view the actual multiplier setting for ports by executing **show running** and looking for an entry in this format:*

spanning-tree < port-list > priority < priority-multiplier >

*For example, configuring port A2 with a priority multiplier of “3” results in this line in the **show running** output:*

spanning-tree A2 priority 3

Syntax: spanning-tree < port-list > root-guard

*MSTP only. When a port is enabled as **root-guard**, it cannot be selected as the root port even if it receives superior STP BPDUs. The port is assigned an “alternate” port role and enters a blocking state if it receives superior STP BPDUs. (A superior BPDU contains “better” information on the root bridge and/or path cost to the root bridge, which would normally replace the current root bridge selection.)*

*The superior BPDUs received on a port enabled as **root-guard** are ignored. All other BPDUs are accepted and the external devices may belong to the spanning tree as long as they do not claim to be the Root device.*

Use this command on MSTP switch ports that are connected to devices located in other administrative network domains to:

- *Ensure the stability of the core MSTP network topology so that undesired or damaging influences external to the network do not enter.*
- *Protect the configuration of the CIST root bridge that serves as the common root for the entire network.*

Default: The root-guard setting is disabled.

Syntax: spanning-tree < port-list > tcn-guard

*When **tcn-guard** is enabled for a port, it causes the port to stop propagating received topology change notifications and topology changes to other ports.*

*(Default: **No** - disabled)*

Configuring BPDU Filtering

The STP BPDU filter feature allows control of spanning-tree participation on a per-port basis. It can be used to exclude specific ports from becoming part of spanning tree operations. A port with the BPDU filter enabled will ignore incoming BPDU packets and stay locked in the spanning-tree forwarding state. All other ports will maintain their role.

Here are some sample scenarios in which this feature may be used:

- To have STP operations running on selected ports of the switch rather than every port of the switch at a time.
- To prevent the spread of errant BPDU frames.
- To eliminate the need for a topology change when a port's link status changes. For example, ports that connect to servers and workstations can be configured to remain outside of spanning-tree operations.
- To protect the network from denial of service attacks that use spoofing BPDUs by dropping incoming BPDU frames. For this scenario, BPDU protection offers a more secure alternative, implementing port shut down and a detection alert when errant BPDU frames are received (see page 4-31 for details).

Caution

Ports configured with the BPDU filter mode remain active (learning and forward frames); however, spanning-tree cannot receive or transmit BPDUs on the port. The port remains in a forwarding state, permitting all broadcast traffic. This can create a network storm if there are any loops (that is, trunks or redundant links) using these ports. If you suddenly have a high load, disconnect the link and disable the bpdu-filter (using the **no** command).

Command Syntax and Example. The following command is used to configure BPDU filters.

Syntax: [no] spanning-tree <port-list | all> bpdu-filter

*Enables/disables the BPDU filter feature on the specified port(s). The bpdu-filter option forces a port to **always** stay in the forwarding state and be excluded from standard STP operation.*

For example, to configure BPDU filtering on port a9, enter:

```
ProCurve(config)# spanning-tree a9 bpdu-filter
```

Viewing BPDU Filtering. The **spanning-tree show <port> configuration** command displays the BPDU's filter state.

```
ProCurve(config)# show spanning-tree a9 config
```

Column showing BPDU filter status											
Port	Type	Path Cost	Prio rity	Admin Edge	Auto Edge	Admin PtP	Hello Time	Root Guard	TCN Guard	BPDU Flt	
A9	100/1000T	Auto	128	No	Yes	True	Global	No	No	Yes	

Figure 4-5. Example of BPDU Filter in Show Spanning Tree Configuration Command

BPDU filters per port are displayed as separate entries of the spanning tree category within the configuration file.

```
ProCurve(config)# show configuration
```

```
...
spanning-tree
spanning-tree A9 bpdu-filter
spanning-tree C7 bpdu-filter
spanning-tree Trk2 priority 4
...
```

Rows showing ports with BPDU filters enabled

Figure 4-6. Example of BPDU Filters in the Show Configuration Command

Configuring BPDU Protection

BPDU protection is a security feature designed to protect the active STP topology by preventing spoofed BPDU packets from entering the STP domain. In a typical implementation, BPDU protection would be applied to edge ports connected to end user devices that do not run STP. If STP BPDU packets are received on a protected port, the feature will disable that port and alert the network manager via an SNMP trap as shown in Figure 4-7.

Figure 4-7. Example of BPDUs Protection Enabled at the Network Edge

The following commands allow you to configure BPDUs protection.

Syntax: [no] spanning-tree <port-list> bpdus-protection

Enables/disables the BPDUs protection feature on a port

Syntax: [no] spanning-tree <port-list> bpdus-protection-timeout <timeout>

*Configures the duration of time when protected ports receiving unauthorized BPDUs will remain disabled. The default value of 0 (zero) sets an infinite timeout (that is, ports that are disabled by **bpdus-protection** are not, by default, re-enabled automatically). (Range: 0-65535 seconds; Default: 0)*

Syntax: [no] spanning-tree trap errant-bpdu

Enables/disables the sending of errant BPDUs traps.

Caution

This command should only be used to guard edge ports that are not expected to participate in STP operations. Once BPDUs protection is enabled, it will disable the port as soon as any BPDUs packet is received on that interface.

Example. To configure BPDU protection on ports 1 to 10 with SNMP traps enabled, enter:

```
ProCurve(config)# spanning-tree 1-10 bpdu protection
ProCurve(config)# spanning-tree trap errant-bpdu
```

The following steps will then be set in process:

1. When an STP BPDU packet is received on ports 1-10, STP treats it as an unauthorized transmission attempt and shuts down the port that the BPDU came in on.
2. An event message is logged and an SNMP notification trap is generated.
3. The port remains disabled until re-enabled manually by a network administrator using the **interface <port-list> enable** command.

Note

To re-enable the bpdu-protected ports automatically, configure a timeout period using the **spanning-tree bpdu-protection-timeout** command.

Viewing BPDU Protection Status. The **show spanning-tree bpdu-protection** command displays a summary listing of ports with BPDU protection enabled. To display detailed per port status information, enter the specific port number(s) as shown in Figure 4-8 below.

Figure 4-8. Example of Show Spanning Tree BPDU Protection Command

BPDU protected ports are displayed as separate entries of the spanning tree category within the configuration file.

```
ProCurve(config)# show configuration
. . .
spanning-tree
spanning-tree A1 bpdu-protection
spanning-tree C7 bpdu-protection
spanning-tree Trk2 priority 4
. . .
```

Rows showing ports with BPDU protection enabled

Figure 4-9. Example of BPDU Filters in the Show Configuration Command

PVST Protection and Filtering

Note

These options are available for switches that support the MSTP protocol only. They are not supported for switches running RSTP.

PVST Protection

If a ProCurve switch in the core of a network receives Per Vlan Spanning Tree (PVST) BPDUs and forwards the unrecognized PVST BPDUs on to MSTP-only switches, those switches then disconnect themselves from the network. This can create instability in the network infrastructure.

When the PVST protection feature is enabled on a port and a PVST BPDU is received on that port, the interface on which the PVST BPDU arrived is shut down, which isolates the sending switch from the rest of the network. An event message is logged and an SNMP notification trap is generated. The errant BPDU counter `hpSwitchStpPortErrantBpduCounter` is incremented. The PVST protection feature is enabled per-port.

Figure 4-10. PVST Switch Being Isolated after Sending a PVST BPDU

Note

This is similar to the BPDU Guard feature where BPDU protection is applied to edge ports connected to end user devices that do not run STP. If STP BPDU packets are received on a protected port, the feature will disable that port and alert the network manager via an SNMP trap.

Syntax: [no] spanning-tree <port-list> pvst-protection

Enables or disables the PVST protection feature on the port or range of ports specified. The command indicates which ports are not expected to receive any PVST BPDUs.

Default: Disabled on all ports

For example, to enable the PVST protection feature on ports 4 through 8, enter this command:

```
ProCurve(config)# spanning-tree 4-8 pvst-protection
```

To disable the PVST protection feature on a port, for example, port 4, use this command:

```
ProCurve(config)# no spanning-tree 4 pvst-protection
```

PVST Filtering

If you configure a port for PVST filtering instead of PVST protection, the port remains in operation but traps are still generated and the BPDU counter `hpSwitchStpPortErrantBpduCounter` is incremented.

Caution

Enabling the PVST filter feature allows the port to continuously forward packets without spanning-tree intervention, which could result in loop formation. If this occurs, disable the port and then reconfigure it with these commands:

```
no spanning-tree <port-list> bpdu-filter
no spanning-tree <port-list> pvst-filter
```

Syntax: [no] spanning-tree <port-list> pvst-filter

Enables or disables the PVST filter feature on the port or range of ports specified. The command indicates which ports are not expected to receive any PVST BPDUs.

Default: Disabled on all ports

```
ProCurve(config)# spanning-tree 8 pvst-filter
```

```
Warning: The BPDU filter allows the port to go into a continuous
forwarding mode and spanning-tree will not interfere, even if
the port would cause a loop to form in the network topology.
If you suddenly experience high traffic load, disable the port
and reconfigure the BPDU filter with the CLI command(s):
    "no spanning-tree PORT_LIST bpdu-filter"
    "no spanning-tree PORT_LIST pvst-filter"
```

Figure 4-11. Example of Enabling PVST Filtering on a Port

Manually Re-enabling a Port

You can re-enable ports manually or use the automatic re-enable timer command as shown:

```
ProCurve(config)# spanning-tree
bpdu-protection-timeout 120
```

Syntax: [no] spanning-tree bpdu-protection-timeout <timeout>

Configures the duration of time protected ports remain disabled. The default value of 0 (zero) sets an infinite timeout (that is, ports that are disabled are not, by default, re-enabled automatically).

Note: This is a GLOBAL command.
(Range: 0-65535 seconds; Default: 0)

You can also set the timeout in the MIB with this MIB object:

hpSwitchStpBpduProtectionTimeout

Showing Ports Configured with PVST Protection and Filtering

To show which ports are configured for PVST protection, enter this command:

ProCurve(config)# show spanning-tree pvst-protection

```
ProCurve(config)# show spanning-tree pvst-protection
Status and Counters - PVST Port(s) BPDU Protection Information
BPDU Protection Timeout (sec) : 0
PVST Protected Ports : 5-6
```

Figure 4-12. Example of Show Spanning-tree Command Displaying All Ports with PVST Protection Enabled

To show which ports are configured for PVST filtering, enter this command:

ProCurve(config)# show spanning-tree pvst-filter

```
ProCurve(config)# show spanning-tree pvst-filter
Status and Counters - PVST Port(s) BPDU Filter Information
PVST Filtered Ports : 8
```

Figure 4-13. Example of Show Spanning-tree Command Displaying All Ports with PVST Filtering Enabled

The **show spanning-tree <port-list> detail** command indicates which ports have PVST protection and/or PVST Filtering enabled.

```
.ProCurve(config)# show spanning-tree 7 detail
.
.
.
Port                               : 7
Status                             : Down
BPDU Protection                     : Yes
BPDU Filtering                     : No
PVST Protection                     : Yes
PVST Filtering                     : No
Errant BPDU Count                   : 0
Root Guard                         : No
TCN Guard                          : No
.
.
.
```

Figure 4-14. Example of Show Spanning-tree Command Displaying PVST Protection Enabled (Yes)

Configuring Loop Protection

You can use BPDU protection for systems that have spanning tree enabled (See “Configuring BPDU Protection” on page 4-30), however, the BPDU protection feature cannot detect the formation of loops when an unmanaged device on the network drops spanning tree packets. To protect against the formation of loops in these cases, you can enable the Loop Protection feature, which provides protection by transmitting loop protocol packets out ports on which loop protection has been enabled. When the switch sends out a loop protocol packet and then receives the same packet on a port that has **send-disable** configured, it shuts down the port from which the packet was sent.

You can configure the **disable-timer** parameter for the amount of time you want the port to remain disabled (0 to 604800 seconds). If you configure a value of zero, the port will not be re-enabled.

To enable loop protection, enter this command:

```
ProCurve(config)# loop-protect <port-list>
```

Syntax: [no] loop-protect <port-list> [receiver-action <send-disable | no-disable> |]
[transmit-interval <1-10>] | [disable-timer <0-604800>] |
[trap <loop-detected>]

Allows you to configure per-port loop protection on the switch.

[receiver-action <send-disable | no-disable>]

Sets the action to be taken when a loop is detected on the port. The port that received the loop protection packet determines what action is taken. If send-disable is configured, the port that transmitted the packet is disabled. If no-disable is configured, the port is not disabled.

Default: send-disable

[trap <loop-detected>]

Allows you to configure loop protection traps. The “loop-detected” trap indicates that a loop was detected on a port.

[disable-timer <0-604800>]

How long (in seconds) a port is disabled when a loop has been detected. A value of zero disables the auto re-enable functionality.

Default: Timer is disabled

[transmit-interval <1-10>]

Allows you to configure the time in seconds between the transmission of loop protection packets.

Default: 5 seconds

To display information about ports with loop protection, enter this command.

Syntax: show loop-protect <port-list>

Displays the loop protection status. If no ports are specified, the information is displayed only for the ports that have loop protection enabled.

Figure 4-15. Example of Show Loop Protect Display

Configuring MST Instance Parameters

When you enable MSTP on the switch, a spanning tree instance is enabled automatically. The switch supports up to sixteen configurable MST instances for each VLAN group that you want to operate as an active topology within the region to which the switch belongs. When creating an instance, you must include a minimum of one VID. You can add more VIDs later if desired.

Command	Page
[no] spanning-tree instance < 1..16 > vlan < vid> [vid..vid]	4-26
no spanning-tree instance < 1..16 >	
spanning-tree instance < 1..16 > priority < 0..15 >	4-40

Syntax: [no] spanning-tree instance < 1..16 > vlan < vid [vid..vid] >
no spanning-tree instance < 1..16 >

Configuring MSTP on the switch automatically configures the IST instance and places all statically and dynamically configured VLANs on the switch into the IST instance. This command creates a new MST instance (MSTI) and moves the VLANs you specify from the IST to the MSTI.

You must map at least one VLAN to an MSTI when you create it. You cannot map a VLAN ID to more than one instance. You can create up to 16 MSTIs in a region.

*The **no** form of the command removes one or more VLANs from the specified MSTI. If no VLANs are specified, the **no** form of the command deletes the specified MSTI.*

When you remove a VLAN from an MSTI, the VLAN returns to the IST instance, where it can remain or be re-assigned to another MSTI configured in the region.

Note: *Starting in software release 13.x.x, you can enter the **spanning-tree instance vlan** command before a static or dynamic VLAN is configured on the switch to preconfigure VLAN ID-to-MSTI mappings. No error message is displayed. Later, each newly configured VLAN that has already been associated with an MSTI is automatically assigned to the MSTI.*

This new default behavior differs from automatically including configured (static and dynamic) VLANs in the IST instance and requiring you to manually assign individual static VLANs to an MSTI.

Syntax: [no] spanning-tree instance < 1..16 > vlan < vid [vid..vid] >
no spanning-tree instance < 1..16 >

— Continued —

Note: The valid VLAN IDs that you can map to a specified MSTI are from 1 to 4094. The VLAN ID-to-MSTI mapping does not require a VLAN to be already configured on the switch. The MSTP VLAN enhancement allows you to preconfigure MSTP topologies before the VLAN IDs associated with each instance exist on a switch.

When you use preconfigured VLAN ID-to-MSTI topologies, ensure that MSTP switches remain in the same region by mapping all VLAN IDs used in the region to the same MSTIs on each regional switch.

When you upgrade switch software to release 13.x.x and later, the existing MSTP topology configuration is automatically saved. All existing VLAN ID-to-MSTI assignments are maintained on a switch for uninterrupted MSTP network operation.

Syntax: spanning-tree instance < 1..16 > priority < priority-multiplier >

This command sets the switch (bridge) priority for the designated instance. This priority is compared with the priorities of other switches in the same instance to determine the root switch for the instance. The lower the priority value, the higher the priority. (If there is only one switch in the instance, then that switch is the root switch for the instance.) The IST regional root bridge provides the path to instances in other regions that share one or more of the same VLAN(s).

The priority range for an MSTP switch is 0-61440. However, this command specifies the priority as a multiplier (0 - 15) of 4096. That is, when you specify a priority multiplier value of 0 - 15, the actual priority assigned to the switch for the specified MST instance is:

$$(\text{priority-multiplier}) \times 4096$$

For example, if you configure “5” as the priority-multiplier for MST Instance 1 on a given MSTP switch, then the **Switch Priority** setting is 20,480 for that instance in that switch.

Note: If multiple switches in the same MST instance have the same priority setting, then the switch with the lowest MAC address becomes the root switch for that instance.

Configuring MST Instance Per-Port Parameters

Command	Page
spanning-tree instance < 1..16 > < port-list > path-cost < auto 1..200000000 >	4-42
spanning-tree instance < 1..16 > < port-list > priority < priority-multiplier >	4-43
spanning-tree < port-list > priority < priority-multiplier >	4-44

Syntax: spanning-tree instance < 1..16 > < port-list > path-cost < auto | 1..200000000 >

*This command assigns an individual port cost for the specified MST instance. (For a given port, the path cost setting can be different for different MST instances to which the port may belong.) The switch uses the path cost to determine which ports are the forwarding ports in the instance; that is which links to use for the active topology of the instance and which ports to block. The settings are either **auto** or in a range from 1 to 200,000,000. With the **auto** setting, the switch calculates the path cost from the link speed:*

10 Mbps — 2000000

100 Mbps — 200000

1 Gbps — 20000

*(Default: **Auto**)*

Syntax: spanning-tree instance < 1..16 > < port-list > priority < priority-multiplier >

This command sets the priority for the specified port(s) in the specified MST instance. (For a given port, the priority setting can be different for different MST instances to which the port may belong.) The priority range for a port in a given MST instance is 0-255. However, this command specifies the priority as a multiplier (0 - 15) of 16. That is, when you specify a priority multiplier of 0 - 15, the actual priority assigned to the switch is:

$$(\text{priority-multiplier}) \times 16$$

*For example, if you configure “2” as the priority multiplier on a given port in an MST instance, then the actual **Priority** setting is 32. Thus, after you specify the port priority multiplier in an instance, the switch displays the actual port priority (and not the multiplier) in the **show spanning-tree instance < 1..16 >** or **show spanning-tree < port-list > instance < 1..16 >** displays. You can view the actual multiplier setting for ports in the specified instance by executing **show running** and looking for an entry in this format:*

spanning-tree instance < 1..15 > < port-list > priority < priority-multiplier >

*For example, configuring port A2 with a priority multiplier of “3” in instance 1, results in this line in the **show running** output:*

spanning-tree instance 1 A2 priority 3

Syntax: spanning-tree < port-list > priority < priority-multiplier >

*This command sets the priority for the specified port(s) for the IST (that is, Instance 0) of the region in which the switch resides. The “priority” component of the port’s “Port Identifier” is set. The Port Identifier is a unique identifier that helps distinguish this switch’s ports from all others. It consists of the Priority value with the port number extension—**PRIORITY:PORT_NUMBER**. A port with a lower value of Port Identifier is more likely to be included in the active topology. This priority is compared with the priorities of other ports in the IST to determine which port is the root port for the IST instance. The lower the priority value, the higher the priority. The IST root port (or trunk) in a region provides the path to connected regions for the traffic in VLANs assigned to the region’s IST instance.*

The priority range for a port in a given MST instance is 0-240. However, this command specifies the priority as a multiplier (0 - 15) of 16. That is, when you specify a priority multiplier of 0 - 15, the actual priority assigned to the switch is:

$$(\text{priority-multiplier}) \times 16$$

*For example, configuring “5” as the priority multiplier on a given port in the IST instance for a region creates an actual **Priority** setting of **80**. Thus, after you specify the port priority multiplier for the IST instance, the switch displays the actual port priority (and not the multiplier) in the **show spanning-tree instance ist** or **show spanning-tree < port-list > instance ist** displays. You can view the actual multiplier setting for ports in the IST instance by executing **show running** and looking for an entry in this format:*

spanning-tree < port-list > priority < priority-multiplier >

*For example, configuring port A2 with a priority multiplier of “2” in the IST instance, results in this line in the **show running** output:*

spanning-tree A2 priority 2

Enabling or Disabling Spanning Tree Operation

This command enables or disables spanning tree operation for any spanning tree protocol enabled on the switch. Before using this command to enable spanning tree, ensure that the version you want to use is active on the switch.

Syntax: [no] spanning-tree

Enabling spanning tree with MSTP configured implements MSTP for all physical ports on the switch, according to the VLAN groupings for the IST instance and any other configured instances. Disabling MSTP removes protection against redundant loops that can significantly slow or halt a network. This command simply turns spanning tree on or off. It does not change the existing spanning tree configuration.

Note

The convergence time for implementing MSTP changes can be disruptive to your network. To minimize such disruption, consider using the **spanning-tree pending** command (refer to the following section on “Enabling an Entire MST Region at Once or Exchanging One Region Configuration for Another”).

Enabling an Entire MST Region at Once or Exchanging One Region Configuration for Another

This operation exchanges the currently active MSTP configuration with the currently pending MSTP configuration. It enables you to implement a new MSTP configuration with minimal network disruption or to exchange MSTP configurations for testing or troubleshooting purposes.

When you configure or reconfigure MSTP, the switch re-calculates the corresponding network paths. This can have a ripple effect throughout your network as adjacent MSTP switches recalculate network paths to support the configuration changes invoked in a single switch. Although MSTP employs rapid spanning-tree operation, the convergence time for implementing MSTP changes can be disruptive to your network. However, by using the **spanning-tree pending** feature, you can set up an MSTP on the switch and then invoke all instances of the new configuration at the same time, instead of one at a time.

Syntax: [no] spanning-tree pending < apply | config-name | config-revision | instance | reset >

This command exchanges the currently active MSTP configuration with the current pending MSTP configuration. Options are as follows:

apply: *Exchanges the currently active MSTP configuration with the pending MSTP configuration.*

config-name: *Specifies the pending MST region name. Must be the same for all MSTP switches in the region. (Default: The switch's MAC address.)*

config-revision: *Specifies the pending MST region configuration revision number. Must be the same for all MSTP switches in the region. (Default: 0).*

instance < 1..16 > vlan < vid | vid-range >: *Creates the pending instance and assigns one or more VLANs to the instance.*

reset: *Copies the switch's currently active MSTP configuration to the pending configuration. This is useful when you want to experiment with the current MSTP configuration while maintaining an unchanged version.*

To Create a Pending MSTP Configuration. This procedure creates a pending MSTP configuration and exchanges it with the active MSTP configuration:

1. Configure the VLANs you want included in any instances in the new region. When you execute the **pending** command, all VLANs configured on the switch will be assigned to a single pending IST instance unless assigned to other, pending MST instances. (The **pending** command creates the region's IST instance automatically.)
2. Configure MSTP as the spanning-tree protocol, then execute **write mem** and reboot. (The pending option is available only with MSTP enabled.)
3. Configure the pending region **config-name** to assign to the switch.
4. Configure the pending **config-revision** number for the region name.
5. If you want an MST instance other than the IST instance, configure the instance number and assign the appropriate VLANs (VIDs) using the **pending instance < 1..16 > vlan < vid | vid-range >** command.
6. Repeat step 5 for each additional MST instance you want to configure.

7. To review your pending configuration, use the **show spanning-tree pending** command (see page 4-62).
8. To exchange the currently active MSTP configuration with the pending MSTP configuration, use the **spanning-tree pending apply** command.

MSTP VLAN Configuration Enhancement

Starting in software release 13.x.x, the MSTP VLAN configuration enhancement allows you to preconfigure an MSTP regional topology and ensure that the same VLAN ID-to-MSTI assignments exist on each MSTP switch in the region.

Caution

When this software version is installed, the prior VLAN ID-to-MSTI mappings do not change. However, this enhancement is not backward-compatible. If you install a software version prior to this version, and you have configured MSTI entries instances mapped to VLANs, they will be removed from the configuration file when booting to the prior version of software. You must do one of the following if you want to install or reload a prior version of the software:

1. Remove all MSTP mappings from the config file and then reconfigure the instance mapping after you are running the desired software version.
2. Save your current configuration file before updating your software to a new version. If you later reload this older version of the software, you can use this configuration file when you reload the older version. See “How to Save Your Current Configuration” on page 4-52.

The default behavior of the **spanning-tree instance vlan** command changes so that, before a static VLAN is configured or a dynamic VLAN is learned on the switch, you can preconfigure its VLAN ID-to-MSTI mapping. Later, when the VLAN is created, it is automatically assigned to the MSTI to which you had previously mapped it.

By supporting preconfigured VLAN ID-to-MSTI topologies, the VLAN Configuration enhancement provides the following benefits:

- **Scalability:** In a network design in which you plan to use a large number of VLANs, you can preconfigure identical VLAN ID-to-MSTI mappings on all switches in a single, campus-wide MST region, regardless of the specific VLANs that you later configure on each switch. After the initial VLAN ID-to-MSTI mapping, you can decide on the exact VLANs that you need on each switch.

All switches in a region must be configured with the same VLAN ID-to-MSTI mappings and the same MSTP configuration identifiers (region name and revision number).

- **Flexibility:** By preconfiguring identical VLAN ID-to-MSTI mappings on all switches in an MST region, you can combine switches that support different maximum numbers of VLANs.
- **Network stability:** You can reduce the interruptions in network connectivity caused by the regeneration of spanning trees in the entire network each time a configuration change in VLAN-to-MSTI mapping is detected on a switch. The negative impact on network performance is reduced if all newly created VLANs are pre-mapped to the correct MST instances. Later, VLAN creation and deletion are ignored by MSTP and no interruption in spanning-tree traffic occurs.
- **Usability:** Dynamically learned GVRP VLANs can be mapped to MSTIs and support MSTP load balancing.

PreConfiguring VLANs in an MST Instance

When you configure an MSTP regional topology, you create multiple spanning-tree instances. Each MST instance provides a fully connected active topology for a particular set of VLANs.

Each switch in an MSTP region is configured with the following set of common parameters:

- Region name (**spanning-tree config-name**)
- Region revision number (**spanning-tree config-revision**)
- Identical VLAN ID-to-MSTI mapping (**spanning-tree instance vlan**)

Each MST instance supports a different set of VLANs. A VLAN that is mapped to an MST instance cannot be a member of another MST instance.

The MSTP VLAN configuration enhancement allows you to ensure that the same VLAN ID-to-MSTI assignments exist on each MSTP switch in a region. Before a static VLAN is configured or a dynamic VLAN is learned on the switch, you can use the **spanning-tree instance vlan** command to map VLANs to each MST instance in the region. Later, when the VLAN is created, the switch automatically assigns it to the MST instance to which you had previously mapped it.

Syntax: [no] spanning-tree instance < 1..16 > vlan < vid [vid..vid] >
no spanning-tree instance < 1..16 >

Configuring MSTP on the switch automatically configures the IST instance and places all statically and dynamically configured VLANs on the switch into the IST instance. This command creates a new MST instance (MSTI) and moves the VLANs you specify from the IST to the MSTI.

You must map at least one VLAN to an MSTI when you create it. You cannot map a VLAN ID to more than one instance. You can create up to 16 MSTIs in a region.

*The **no** form of the command removes one or more VLANs from the specified MSTI. If no VLANs are specified, the **no** form of the command deletes the specified MSTI.*

When you remove a VLAN from an MSTI, the VLAN returns to the IST instance, where it can remain or be re-assigned to another MSTI configured in the region.

Note: *The valid VLAN IDs that you can map to a specified MSTI are from 1 to 4094. The VLAN ID-to-MSTI mapping does not require a VLAN to be already configured on the switch. The MSTP VLAN enhancement allows you to preconfigure MSTP topologies before the VLAN IDs associated with each instance exist on a switch.*

When you use preconfigured VLAN ID-to-MSTI topologies, ensure that MSTP switches remain in the same region by mapping all VLAN IDs used in the region to the same MSTIs on each regional switch.

Configuring MSTP Instances with the VLAN Range Option

For the switches covered in this guide, if you use the **spanning-tree instance** command with the VLAN range option, even if the range includes VLANs that are not currently present on the switch, the entire range of VLANs is configured. For example, if VLANs 1, 5, and 7 are currently present and you enter this command:

```
ProCurve(config)# spanning-tree instance 1 vlan 1-10
```

then all the VLANs from 1 through 10 are included, even those VLANs that are not present.

On other ProCurve switches, only the VLANs that are present will be included, that is, only VLANs 1, 5, and 7 would be included. The switch will map these VLANs to MSTP Instance 1, which results in a Configuration Digest that is not the same as the Configuration Digest for the Series 3500/5400/6200/2900 switches running this enhancement. (See Figure 4-16 and Figure 4-17)

Figure 4-16 shows an example of an MSTP instance configured with the VLAN range option. All the VLANs are included in the instance whether they exist or not. Figure 4-17 shows an example of an MSTP instance configured on a ProCurve switch other than the Series 3500/5400/6200/2900. Only VLANs 1, 5, and 7 are included in the instance.

```
ProCurve(config)# show spanning-tree mst-config

MST Configuration Identifier Information
MST Configuration Name: MSTP1
MST Configuration Revision: 1
MST Configuration Digest: [ 0x51B7EBA6BEE8702D2BA4497D4367517 ]

IST Mapped VLANs :

Instance ID Mapped VLANs
-----
1           1-10
```

Figure 4-16. An Example of Mapping VLANs with the Range Option where all VLANs are Included

The Configuration Digest value in Figure 4-17 is not the same as in Figure 4-16, indicating that these switches do not operate in the same instance.

The Common Spanning Tree (CST) will still have the correct root associations.

```
ProCurve(config)# show spanning-tree mst-config

MST Configuration Identifier Information
MST Configuration Name: MSTP1
MST Configuration Revision: 1
MST Configuration Digest: [ 0x89D3ADV471668D6D832F6EC4AA9CF4AA ]

IST Mapped VLANs :

Instance ID Mapped VLANs
-----
1           1, 5, 7
```

Figure 4-17. Example of Mapping VLANs on Switches other than ProCurve Series 3500/5400/6200/2900

Operating Notes for the VLAN Configuration Enhancement

- Configuring MSTP on the switch automatically configures the Internal Spanning Tree (IST) instance and places all statically and dynamically configured VLANs on the switch into the IST instance. The spanning-tree instance vlan command creates a new MST instance and moves the VLANs you specify from the IST to the MSTI.

You must map a least one VLAN ID to an MSTI when you create it. You cannot map a VLAN ID to more than one instance. You can create up to 16 MSTIs in a region.

- The **no** form of the spanning-tree instance vlan command removes one or more VLANs from the specified MSTI. If no VLANs are specified, the **no** form of the command deletes the specified MSTI.

When you remove a VLAN from an MSTI, the VLAN returns to the IST instance, where it can remain or be re-assigned to another MSTI configured in the region.

- If you enter the spanning-tree instance vlan command before a static or dynamic VLAN is configured on the switch to preconfigure VLAN ID-to-MSTI mappings, no error message is displayed. Later, each newly configured VLAN that has already been associated with an MSTI is automatically assigned to the MSTI.

This new default behavior differs from automatically including configured (static and dynamic) VLANs in the IST instance and requiring you to manually assign individual static VLANs to an MSTI.

- The valid VLAN IDs that you can map to a specified MSTI are from 1 to 4094. The VLAN ID-to-MSTI mapping does not require a VLAN to be already configured on the switch. The MSTP VLAN enhancement allows you to preconfigure MSTP topologies before the VLAN IDs associated with each instance exist on a switch.
- When you use preconfigured VLAN ID-to-MSTI topologies, ensure that MSTP switches remain in the same region by mapping all VLAN IDs used in the region to the same MSTIs on each regional switch.
- When you upgrade switch software to release K.13.XX and later, the existing MSTP topology configuration is automatically saved. All existing VLAN ID-to-MSTI assignments are maintained on a switch for uninterrupted MSTP network operation.

How to Save Your Current Configuration

You can save your current configuration before updating to a new version of software by following these steps:

1. Enter the **show config files** command to display your current configuration files, as shown in Figure 4-18.

```
ProCurve(config)# show config files
```

Configuration files:

id	act	pri	sec	name
1	*	*	*	config1
2				config2
3				

Figure 4-18. An Example of the show config files Command Output

2. To save a configuration file for software version T.12.43, enter this command:

```
ProCurve(config)# copy config config1 config  
configT1243.cfg
```

You can choose any name for the saved configuration file that you prefer.

3. Display the configuration files as shown in Figure 4-19. You will see your newly created configuration file listed.

```
ProCurve(config)# show config files
```

Configuration files:

id	act	pri	sec	name
1	*	*	*	config1
2				config2
3				configT1243.cfg

Figure 4-19. A Config File for the Current Software Version is Created

4. Now update your switch to the desired version, for example, T.12.51. Enter the **show flash** command to see the results. The switch is now running the software version T.12.51.

```
ProCurve(config)# show flash
```

Image	Size(Bytes)	Date	Version
Primary Image	: 6771179	10/15/07	T.12.51
Secondary Image	: 7408949	08/24/07	T.12.43
Boot Rom Version:	K.12.12		
Default Boot	: Primary		

Figure 4-20. Show Flash Command after Upgrading the Switch to a New Version of the Software (T.12.51)

5. If you want to run the prior software version, T.12.43 in this example, enter this command:

```
ProCurve(config)# boot system flash secondary config  
configT1243.cfg
```

After rebooting, the switch is running software version T.12.43 and is using the configuration file that you saved for this software version, configT1243.cfg.

You can also save the T.12.43 configuration file on a TFTP server. If you wanted to reload the T.12.43 version of the software again, reload the configuration file before you do the reload.

Displaying MSTP Statistics and Configuration

Command	Page
MSTP Statistics:	
show spanning-tree [< port-list>]	below
show spanning-tree [< port-list>] detail	4-57
show spanning-tree instance < ist 1..16 >	4-58
MSTP Configuration	
show spanning-tree [port-list] config	4-59
show spanning-tree [port-list] config instance < ist 1..16 >	4-60
show spanning-tree mst-config	4-61
show spanning-tree pending < < instance ist > mst-config >	4-62

SNMP MIB Support for MSTP. MSTP is a superset of the STP/802.1D and RSTP/802.1w protocols and uses the MIB objects defined for these two protocols.

Displaying Global MSTP Status

The following commands display the MSTP statistics for the connections between MST regions in a network.

Syntax: show spanning-tree

*This command displays the switch's global and regional spanning-tree status, plus the per-port spanning-tree operation at the regional level. Note that values for the following parameters appear only for ports connected to active devices: **Designated Bridge, Hello Time, Ptp, and Edge.***

Syntax: show spanning-tree < port-list >

This command displays the spanning-tree status for the designated port(s). You can list data for a series of ports and port trunks by specifying the first and last port or trunk of any consecutive series of ports and trunks. For example, to display data for port A20-A24 and trk1, you would use this command:
show spanning-tree a20-a42,trk1

Multiple Instance Spanning-Tree Operation

Displaying MSTP Statistics and Configuration

Figure 4-21. Example of Common Spanning Tree Status

Displaying Detailed Port Information

The following commands display the MSTP statistics for the connections between MST regions in a network.

Syntax: show spanning-tree detail

This command displays additional parameters concerning the common spanning tree (CST) ports.

Syntax: show spanning-tree < port-list > detail

This command displays detailed spanning-tree status for the designated port(s).

ProCurve# show spanning-tree a9 detail

Status and Counters - CST Port(s) Detailed Information

Port	: A9	Gives information concerning the Common Spanning Tree (CST) only. Use the show spanning-tree instance commands to view counters pertaining to particular IST instances.

Figure 4-22. Example of CST Port Information using Show Spanning Tree Detail Command

Note

This command gives information about the CST only. To view details of specific MST Instances, use the **show spanning tree instance** commands.

Displaying Status for a Specific MST Instance

The following commands display the MSTP statistics for a specified MST instance.

Syntax: show spanning-tree instance < ist | 1..16 >

This command displays the MSTP statistics for either the IST instance or a numbered MST instance running on the switch.

Syntax: show spanning-tree instance < ist | 1..16 > detail

This command displays status on all active ports for a specific instance of MSTP.

Syntax: show spanning-tree < port-list > instance < ist | 1..16 > detail

This command displays detailed status for the designated port(s) for a specific instance of MSTP.

Switch-1(config)# show spanning-tree instance 1						
MST Instance Information						
Instance ID : 1						
Mapped VLANs : 11,22						
Switch Priority : 32768						
Topology Change Count : 4						
Time Since Last Change : 6 secs

Figure 4-23. Example of MSTP Statistics for a Specific Instance on an MSTP Switch

Displaying the MSTP Configuration

Displaying the Global MSTP Configuration. This command displays the switch's basic and MST region spanning-tree configuration, including basic port connectivity settings.

Syntax: show spanning-tree config

*The upper part of this output shows the switch's global spanning-tree configuration that applies to the MST region. The port listing shows the spanning-tree port parameter settings for the spanning-tree region operation (configured by the **spanning-tree <port-list>** command). For information on these parameters, refer to "Configuring MSTP Per-Port Parameters" on page 4-25.*

Syntax: show spanning-tree <port-list> config

*This command shows the same data as the above command, but lists the spanning-tree port parameter settings for only the specified port(s) and/or trunk(s). You can list data for a series of ports and port trunks by specifying the first and last port or trunk of any consecutive series of ports and trunks. For example, to display data for port A20-A24 and trk1, use this command: **show spanning-tree a20-a24,trk1 config***

Switch-2(config)# show spanning-tree config							
Multiple Spanning Tree (MST) Configuration Information							
STP Enabled [No] : Yes							
Force Version [MSTP-operation] : MSTP-operation

Trk1		Auto	128	Yes	Force-True	Yes	Use Global

Figure 4-24. Example of Displaying the Switch's Global Spanning-Tree Configuration

Displaying Per-Instance MSTP Configurations. These commands displays the per-instance port configuration and current state, along with instance identifiers and regional root data.

Syntax: show spanning-tree config instance < ist | 1..16 >

The upper part of this output shows the instance data for the specified instance. The lower part of the output lists the spanning-tree port settings for the specified instance.

Syntax: show spanning-tree < port-list > config instance < ist | 1..16 >

This command shows the same data as the above command, but lists the spanning-tree port parameter settings for only the specified port(s) and/or trunk(s). You can list data for a series of ports and port trunks by specifying the first and last port or trunk of any consecutive series of ports and trunks. For example, to display data for port A20-A24 and trk1, use this command:

show spanning-tree a20-a24,trk1 config instance 1

```
Switch-2(config)# show spanning-tree config instance 1
```

MST Instance Configuration Information			
[Instance ID : 1			
Switch Priority : 32768]			
Mapped VLANs : 11,22			

Port	Type	Cost	Priority
A3	10/100TX	Auto	128
A4	10/100TX	Auto	128
A5	10/100TX	Auto	128
.	.	.	.
A23	10/100TX	Auto	128
A24	10/100TX	Auto	128
Trk1		100000	128

Figure 4-25. Example of the Configuration Listing for a Specific Instance

Displaying the Region-Level Configuration in Brief. This command output is useful for quickly verifying the allocation of VLANs in the switch's MSTP configuration and for viewing the configured region identifiers.

Syntax: show spanning-tree mst-config

This command displays the switch's regional configuration.

Note: The switch computes the **MSTP Configuration Digest** from the VID to MSTI configuration mappings on the switch itself. As required by the 802.1s standard, all MSTP switches within the same region must have the same VID to MSTI assignments, and any given VID can be assigned to either the IST or one of the MSTIs within the region. Thus, the MSTP Configuration Digest must be identical for all MSTP switches intended to belong to the same region. When comparing two MSTP switches, if their Digest identifiers do not match, then they cannot be members of the same region.

```
Switch-2(config)# show spanning-tree mst-config

MST Configuration Identifier Information

MST Configuration Name : REGION_1
MST Configuration Revision : 1
MST Configuration Digest : 0xDAD6A13EC5141980B7EBDA71D8991E7C

IST Mapped VLANs : 1,66

Instance ID Mapped VLANs
-----
1          11,22
2          33,44,55
```

Refer to the "Note", above.

Figure 4-26. Example of a Region-Level Configuration Display

Displaying the Pending MSTP Configuration. This command displays the MSTP configuration the switch will implement if you execute the spanning-tree pending apply command (Refer to “Enabling an Entire MST Region at Once or Exchanging One Region Configuration for Another” on page 4-45.)

Syntax: show spanning-tree pending < instance | mst-config >

instance < 1..16 | ist >

Lists region, instance I.D. and VLAN information for the specified, pending instance.

mst-config

Lists region, IST instance VLAN(s), numbered instances, and assigned VLAN information for the pending MSTP configuration.

```
ProCurve# show spanning-tree pending instance 1

Pending MST Instance Configuration Information

MST Configuration Name : New-Version_01
MST Configuration Revision : 10
Instance ID : 1
Mapped VLANs : 1,22

Switch-1(config)# show spanning-tree pending mst-config

Pending MST Configuration Identifier Information

MST Configuration Name : New-Version_01
MST Configuration Revision : 10

IST Mapped VLANs : 11,33

Instance ID Mapped VLANs
-----
1             1,22
```

Figure 4-27. Example of Displaying a Pending Configuration

Troubleshooting an MSTP Configuration

Command	Page
show spanning-tree root-history	4-63
show spanning-tree debug counters	4-66
show spanning-tree debug-counters instance < instance-id >	4-67
show spanning-tree debug-counters instance < instance-id > ports <port-list>	4-69

This section describes the **show spanning-tree** commands that you can use to monitor, troubleshoot, and debug the operation of a multiple-instance spanning-tree configuration in your network.

Note that the **show spanning-tree** commands described in this section allow you to troubleshoot MSTP activity in your network by focusing on increasingly specific levels of operation. For example, you can display debug information for:

- All MST instances
- All ports used in one MST instance
- A specific port or several ports used in one MST instance

Also, you can display the change history for the root (bridge) switch used as the single forwarding path for:

- All MST regions, STP bridges, and RSTP bridges in an STP network
- All VLANs on MSTP switches in a region
- All VLANs on MSTP switches in an MST instance

Displaying the Change History of Root Bridges

The **show spanning-tree root-history** command allows you to display change history information (up to 10 history entries) for a specified root bridge in any of the following MSTP topologies:

- Common Spanning Tree (**cst**): Provides connectivity in a bridged network between MST regions, STP LANs, and RSTP LANs.
- Internal Spanning Tree (**ist**): Provides connectivity within an MST region for VLANs associated with the default Common and Internal Spanning Tree (CIST) instance in your network (VLANs that have not been mapped to an MST instance).

- **MST Instance (mst):** Connects all static and (starting from release 13.x.x) dynamic VLANs assigned to a multiple spanning-tree instance.

Syntax: show spanning-tree root-history <cst | ist | mst <instance-id>>

This command displays the change history for the root bridge in the specified MSTP topology.

*The **cst** parameter displays the change history for the root bridge of a spanning-tree network, including MST regions and STP and RSTP bridges.*

*The **ist** parameter displays the change history for the root bridge in the IST instance of an MST region.*

*The **mst** <instance-id> parameter displays the change history for the root bridge in an MST instance, where <instance-id> is an ID number from 1 to 16.*

Use the **show spanning-tree root-history** command to view the number and dates of changes in the assignment of a root bridge. Possible intrusion into your MST network may occur if an unauthorized external device gains access to a spanning tree by posing as the root device in a topology. To prevent an MST port connected to the device from being selected as the root port in a topology, use the **spanning-tree root-guard** command.

The following examples show sample output of the **show spanning-tree root-history** command for different MSTP topologies. Note that in each example, the root bridge ID is displayed in the format:
<priority:mac-address>

Where:

- <priority> is the MSTP switch priority calculated for one of the following:
 - The IST (regional) root switch using the **spanning-tree priority** command
 - An MSTI root switch using the **spanning-tree instance priority** command
- <mac-address> is the MAC address of the root (bridge) switch.

```
ProCurve(config)# show spanning-tree root-history cst
```

Status and Counters - CST Root Changes History

MST Instance ID : 0
 Root Changes Counter : 2
 Current Root Bridge ID : 32768:000883-024500

Root Bridge ID	Date	Time
32768:000883-024500	02/09/07	17:40:59
36864:001279-886300	02/09/07	17:40:22

Identifies the root bridge of the common spanning tree in a bridged network that connects different MST regions and STP or RSTP devices.

Figure 4-28. Example of show spanning-tree root-history cst Command Output

```
ProCurve(config)# show spanning-tree root-history ist
```

Status and Counters - IST Regional Root Changes History

MST Instance ID : 0
 Root Changes Counter : 2
 Current Root Bridge ID : 32768:000883-024500

Root Bridge ID	Date	Time
32768:000883-024500	02/09/07	17:40:59
36864:001279-886300	02/09/07	17:40:22

Identifies the root bridge of the internal spanning tree in an MST region.

Figure 4-29. Example of show spanning-tree root-history ist Command Output

```
ProCurve(config)# show spanning-tree root-history mst 2
```

Status and Counters - MST Instance Regional Root Changes History

MST Instance ID : 2
 Root Changes Counter : 2
 Current Root Bridge ID : 32770:000883-024500

Root Bridge ID	Date	Time
32770:000883-024500	02/09/07	17:40:59
32770:001279-886300	02/09/07	17:40:22

Identifies the root bridge of an MST instance in an MST region.

Figure 4-30. Example of show spanning-tree root-history msti Command Output

Displaying Debug Counters for All MST Instances

The **show spanning-tree debug-counters** command allows you to display the aggregate values of all MSTP debug counters that are maintained on a switch. These aggregate values are a summary of the information collected from all ports and from all spanning-tree instances that forward traffic on switch ports.

Use the displayed diagnostic information to globally monitor MSTP operation on a per-switch basis.

Syntax: show spanning-tree debug-counters

This command displays debug counters for MSTP activity on all ports configured for VLANs used in spanning-tree instances.

The following example shows sample output of the **show spanning-tree debug-counters** command for all ports. For a description of each counter, refer to Table 4-1 on page 4-71..

```
ProCurve(config)# show spanning-tree debug-counters
```

Status and Counters - MSTP Bridge Common Debug Counters Information		
Counter Name	Aggregated Value	Collected From
Invalid BPDUs	0	CIST

Figure 4-31. Example of show spanning-tree debug-counters Command Output

Displaying Debug Counters for One MST Instance

The **show spanning-tree debug-counters instance** command allows you to display the aggregate values of all MSTP debug counters maintained on a switch for a specified spanning-tree instance. These aggregate values are a summary of information collected from all ports that have VLANs assigned to the specified instance.

Use the **show spanning-tree debug-counters instance** command to troubleshoot the global MSTP diagnostic information displayed in **show spanning-tree debug-counters** command output when you suspect unauthorized MSTP activity in a specific MST instance.

Syntax: show spanning-tree debug-counters instance <instance-id>

This command displays debug counters for MSTP activity on all ports configured for VLANs in the specified MST instance.

*The valid values for **instance** <instance-id> are from 0 to 16:*

- 0 specifies the default MST (CIST) instance.
- 1 to 16 specify a multiple spanning-tree (MST) instance.

The following example shows sample output of the **show spanning-tree debug-counters instance** command when applied to the Common and Internal Spanning Tree (CIST) instance (default MST instance 0) in the network. For a description of each counter, refer to Table 4-1 on page 4-71.

ProCurve(config)# show spanning-tree debug-counters instance 0		
Status and Counters - CIST Common Debug Counters Information		
MST Instance ID : 0		
Counter Name	Aggregated Value	Collected From
-----	-----	-----
Invalid BPDUs	0	Ports
Errant BPDUs	172603	Ports
MST Config Error BPDUs	0	Ports
Looped-back BPDUs	0	Ports
Starved BPDUs	0	Ports
Exceeded Max Age BPDUs	0	Ports
Exceeded Max Hops BPDUs	0	Ports
Topology Changes Detected	1	Ports

MST BPDUs Rx	172577	Ports

Figure 4-32. Example of show spanning-tree debug-counters instance Command Output for All Ports in the CIST Instance

Displaying Debug Counters for Ports in an MST Instance

The **show spanning-tree debug-counters instance ports** command allows you to display the aggregate values of all MSTP debug counters maintained on one or more ports used by a specified spanning-tree instance. These aggregate values are a summary of information collected from the specified ports that have VLANs assigned to the specified instance.

Use the **show spanning-tree debug-counters instance ports** command to troubleshoot at a finer level the more general MSTP diagnostic information displayed in **show spanning-tree debug-counters instance** command output when you suspect unauthorized MSTP activity on one or more MST ports in an MST instance.

Syntax: show spanning-tree debug-counters instance <instance-id>
ports <port-list>

This command displays debug counters for MSTP activity on the specified ports configured for VLANs in the specified MST instance.

*The valid values for **instance** <instance-id> are from 0 to 16:*

- 0 specifies the default MST (CIST) instance.
- 1 to 16 specify an MST instance.

*The **ports** <port-list> parameter specifies one or more MST ports or trunk ports.*

*In the port list, enter a series of ports by separating the first and last ports in the series with a dash (-); for example, **a2-a8** or **trk1-trk3**. Separate individual ports and series of ports with a comma; for example, **a2-a8, a20, trk1, trk4-trk5**.*

The following examples shows sample output of the **show spanning-tree debug-counters instance ports** command for both the CIST (default MST instance 0) and an MST instance (instance 2) on port A15. For a description of each counter, refer to Table 4-1 on page 4-71.

```
ProCurve(config)# show spanning-tree debug-counters instance 0 ports a15
```

Field Descriptions in MSTP Debug Command Output

Table 4-1 contains descriptions of the debugging information displayed in the output of **show spanning-tree debug-counters** commands.

Table 4-1. MSTP Debug Command Output: Field Descriptions

Field	Description
Invalid BPDUs	Number of received BPDUs that failed standard MSTP (802.1Q-REV/D5.0 14.4) validation checks and were dropped. This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
Errant BPDUs	Number of received BPDUs that were dropped on a port that is configured to not expect BPDU packets. This counter is maintained by the CIST (default MST instance 0 in the network) on a per-port basis and is incremented each time a BPDU packet is received on a port configured with the BPDU filter to ignore incoming BPDU packets (spanning-tree bpd-filter command) or the BPDU protection feature to disable the port when BPDU packets are received (spanning-tree bpd-protection command).

Multiple Instance Spanning-Tree Operation

Troubleshooting an MSTP Configuration

Field	Description
MST Config Error BPDUs	Number of BPDUs received from a neighbor bridge with inconsistent MST configuration information. For example, BPDUs from a transmitting bridge may contain the same MST configuration identifiers (region name and revision number) and format selector as the receiving bridge, but the value of the Configuration Digest field (VLAN ID assignments to regional IST and MST instances) is different. This difference indicates a probable configuration error in MST region settings on the communicating bridges. The received BPDU is still processed by MSTP. This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
Looped-back BPDUs	Number of times a port has received self-sent BPDU packets as the result of an external loop condition in which the BPDUs were looped back to the originating transmission port. The received BPDU is still processed by MSTP and the port changes to a blocked state. This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
Starved BPDUs	Number of times that no BPDUs are received within the scheduled interval (three times the Hello Time value configured with the spanning-tree hello-time command) from a downstream CIST-designated peer port on the CIST root, alternate, or backup port. As a result, the "starved" port triggers a spanning-tree topology regeneration. This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
Starved MSTI MSGs	Number of times that no BPDUs are received within the scheduled interval (three times the Hello Time value configured with the spanning-tree hello-time command) from a downstream MSTI-designated peer port on the MSTI root, alternate, or backup port. As a result, the "starved" port triggers a spanning-tree topology regeneration. This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
Exceeded Max Age BPDUs	Number of times that a BPDU packet is received from a bridge external to the MST region with a Message Age value greater than the configured value of the Max Age parameter (spanning-tree maximum age command). This may occur if the receiving bridge is located too far from the root bridge (beyond the configured size of the spanning-tree domain on the root bridge) or if a BPDU packet with invalid root information is continuously circulating between bridges in a spanning-tree domain and needs to be aged out. This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
Exceeded Max Hops BPDUs	Number of times that a BPDU packet is received from a bridge internal to the MST region with a CIST Remaining Hops value less than or equal to 1. This may occur if the receiving bridge is located too far from the CIST regional root bridge (beyond the configured size of the MST region on the CIST regional root bridge) or if a PDU packet with invalid CIST regional root bridge information is continuously circulating between bridges in the MST Region and needs to be aged out. This counter is maintained by the CIST (default MST instance 0 in the region) on a per-port basis.

Field	Description
Exceeded Max Hops MSTI MSGs	Number of times that an MSTI MSG packet is received from a bridge internal to the MST region with an MSTI Remaining Hops value less than or equal to 1. This may occur if the receiving bridge is located too far from the MSTI regional root bridge (beyond the configured size of the MST region on the MSTI regional root bridge) or if a BPDU packet with invalid MSTI regional root bridge information is continuously circulating between bridges in an MST region and needs to be aged out. This counter is maintained on a per-MSTI per-port basis.
Topology Changes Detected	Number of times that a Topology Change event is detected by the CIST or MSTI port and the port triggers a topology change propagation throughout the network. A Topology Change event occurs when a non-edge port enters forwarding state. This counter is maintained on a per-CIST per-port and on a per-MSTI per-port basis.
Topology Changes Tx	Number of times that Topology Change information is propagated (sent out) through the port to the rest of the network. For a CIST port, the counter is the number of times that a CFG, RST or MST BPDU with the TC flag set is transmitted out of the port. For an MSTI port, the counter is the number of times that a MSTI configuration message with the TC flag set is transmitted out of the port. This counter is maintained on a per-CIST per-port and on a per-MSTI per-port bases.
Topology Changes Rx	Number of times that Topology Change information is received from the peer port. For a CIST port, the counter is the number of times that a CFG, RST or MST BPDU with the TC flag set is received. For an MSTI port, the counter is the number of times that an MSTI configuration message with the TC flag set is received. This counter is maintained on a per-CIST per-port and on a per-MSTI per-port basis.
Topology Change ACKs Tx	Number of times that the Topology Change acknowledgement is transmitted through the port (number of CFG, RST or MST BPDUs transmitted with the Topology Change Acknowledge flag set). This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
Topology Change ACKs Rx	Number of times the Topology Change acknowledgement is received on the port (number of CFG, RST or MST BPDUs received with the Topology Change Acknowledge flag set). This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
TCN BPDUs Tx	Number of Topology Change Notification BPDUs that are transmitted through the port. This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
TCN BPDUs Rx	Number of Topology Change Notification BPDUs that are received on the port. This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
CFG BPDUs Tx	Number of (802.1D) Configuration BPDUs that are transmitted through the port. This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
CFG BPDUs Rx	Number of (802.1D) Configuration BPDUs that are received on the port. This counter is maintained by the CIST (default MST instance 0) on a per-port basis.

Field	Description
RST BPDUs Tx	Number of (802.1w) RST BPDUs that are transmitted through the port. This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
RST BPDUs Rx	Number of (802.1w) RST BPDUs that are received on the port. This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
MST BPDUs Tx	Number of (802.1s) MST BPDUs that are transmitted through the port. This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
MST BPDUs Rx	Number of (802.1s) MST BPDUs that are received on the port. This counter is maintained by the CIST (default MST instance 0) on a per-port basis.
MSTI MSGs Tx	Number of times that a configuration message for a specific MSTI was encoded in (802.1s) MST BPDUs that are transmitted through the port. This counter is maintained on a per-MSTI per-port basis.
MSTI MSGs Rx	Number of times that the MSTI detected a configuration message destined to the MSTI in (802.1s) MST BPDUs received on the port. This counter is maintained on a per-MSTI per-port basis.

Troubleshooting MSTP Operation

Table 4-2. Troubleshooting MSTP Operation

Problem	Possible Cause
Duplicate packets on a VLAN, or packets not arriving on a LAN at all.	The allocation of VLANs to MSTIs may not be identical among all switches in a region.
A switch intended to operate in a region does not receive traffic from other switches in the region.	An MSTP switch intended for a particular region may not have the same configuration name or region revision number as the other switches intended for the same region. The MSTP configuration name (spanning-tree config-name command) and MSTP configuration revision number (spanning-tree config-revision command) must be identical on all MSTP switches intended for the same region. Another possible cause is that the set of VLANs and VLAN ID-to-MSTI mappings (spanning-tree instance vlan command) configured on the switch may not match the set of VLANs and VLAN ID-to-MSTI mappings configured on other switches in the intended region.

As the term suggests, *network policy* refers to the network-wide controls you can implement to:

- Ensure uniform and efficient traffic handling throughout your network, while keeping the most important traffic moving at an acceptable speed, regardless of current bandwidth usage.
- Exercise control over the priority settings of inbound traffic arriving in and travelling through your network.

Adding bandwidth is often a good idea, but it is not always feasible and does not completely eliminate the potential for network congestion. There will always be points in the network where multiple traffic streams merge or where network links will change speed and capacity. The impact and number of these congestion points will increase over time as more applications and devices are added to the network.

When (not *if*) network congestion occurs, it is important to move traffic on the basis of relative importance. However, without *Quality of Service* (QoS) prioritization, less important traffic can consume network bandwidth and slow down or halt the delivery of more important traffic. That is, without QoS, most traffic received by the switch is forwarded with the same priority it had upon entering the switch. In many cases, such traffic is “normal” priority and competes for bandwidth with all other normal-priority traffic, regardless of its relative importance to your organization’s mission.

Quality of Service (QoS): Managing Bandwidth More Effectively

Introduction

This section gives an overview of QoS operation and benefits, and describes how to configure QoS in the console interface.

Quality of Service is a general term for classifying and prioritizing traffic throughout a network. That is, QoS enables you to establish an end-to-end traffic priority policy to improve control and throughput of important data. You can manage available bandwidth so that the most important traffic goes first. For example, you can use Quality of Service to:

- Upgrade or downgrade traffic from various servers.
- Control the priority of traffic from dedicated VLANs or applications.
- Change the priorities of traffic from various segments of your network as your business needs change.
- Set priority policies in edge switches in your network to enable traffic-handling rules across the network.

Figure 5-1. Example of 802.1p Priority Based on CoS (Class-of-Service) Types and Use of VLAN Tags

Figure 5-2. Example Application of Differentiated Services Codepoint (DSCP) Policies

At the edge switch, QoS classifies certain traffic types and in some cases applies a DSCP policy. At the next hop (downstream switch) QoS honors the policies established at the edge switch. Further downstream, another switch may reclassify some traffic by applying new policies, and yet other downstream switches can be configured to honor the new policies.

QoS is implemented in the form of rules or policies that are configured on the switch. While you can use QoS to prioritize only the outbound traffic while it is moving through the switch, you derive the maximum benefit by using QoS in an 802.1Q VLAN environment (with 802.1p priority tags) or in an untagged VLAN environment (with DSCP policies) where QoS can set priorities that downstream devices can support without re-classifying the traffic.

By prioritizing traffic, QoS supports traffic growth on the network while optimizing the use of existing resources—and delaying the need for further investments in equipment and services. That is, QoS enables you to:

- Specify which traffic has higher or lower priority, regardless of current network bandwidth or the relative priority setting of the traffic when it is received on the switch.
- Change (upgrade or downgrade) the priority of outbound traffic.
- Override “illegal” packet priorities set by upstream devices or applications that use 802.1Q VLAN tagging with 802.1p priority tags.
- Avoid or delay the need to add higher-cost NICs (network interface cards) to implement prioritizing. (Instead, control priority through network policy.)

QoS on the switches covered in this guide support these types of traffic marking:

- **802.1p prioritization:** Controls the outbound port queue priority for traffic leaving the switch, and (if traffic exits through a VLAN-tagged port) sends the priority setting with the individual packets to the downstream devices.
- **IP Type-of-Service (ToS):** Enables the switch to set, change, and honor prioritization policies by using the Differentiated Services (diffserv) bits in the ToS byte of IPv4 packet headers.

Terminology

Term	Use in This Document
802.1p priority	A traffic priority setting carried by a VLAN-tagged packet moving from one device to another through ports that are tagged members of the VLAN to which the packet belongs. This setting can be from 0 - 7. The switch handles an outbound packet on the basis of its 802.1p priority. However, if the packet leaves the switch through a VLAN on which the port is an untagged member, this priority is dropped, and the packet arrives at the next, downstream device without an 802.1p priority assignment.
802.1Q field	A four-byte field that is present in the header of Ethernet packets entering or leaving the switch through a port that is a tagged member of a VLAN. This field includes an 802.1p priority setting, a VLAN tag, or ID number (VID), and other data. A packet entering or leaving the switch through a port that is an untagged member of the outbound VLAN does not have this field in its header and thus does not carry a VID or an 802.1p priority. See also “802.1p priority”.
codepoint	Refer to DSCP, below.
downstream device	A device linked directly or indirectly to an outbound switch port. That is, the switch <u>sends traffic to</u> downstream devices.
DSCP	<i>Differentiated Services Codepoint</i> . (Also termed <i>codepoint</i> .) A DSCP is comprised of the upper six bits of the ToS (Type-of-Service) byte in IP packets. There are 64 possible codepoints. In the default QoS configuration for the switches covered in this guide, some codepoints are configured with default 802.1p priority settings for Assured-Forwarding and Expedited Forwarding. All other codepoints are unused (and listed with No-override for a priority).
DSCP policy	A DSCP configured with a specific 802.1p priority (0- 7). (Default: No-override). Using a DSCP policy, you can configure the switch to assign priority to IP packets. That is, for an IP packet identified by the specified classifier, you can assign a new DSCP and an 802.1p priority (0-7). For more on DSCP, refer to “Details of QoS IP Type-of-Service” on page 5-38. For the DSCP map, see figure 5-17 on page 5-39.
edge switch	In the QoS context, this is a switch that receives traffic from the edge of the LAN or from outside the LAN and forwards it to devices within the LAN. Typically, an edge switch is used with QoS to recognize packets based on classifiers such as TCP/UDP application type, IP-device (address), Protocol (LAN), VLAN-ID (VID), and Source-Port (although it can also be used to recognize packets on the basis of ToS bits). Using this packet recognition, the edge switch can be used to set 802.1p priorities or DSCP policies that downstream devices will honor.
inbound port	Any port on the switch through which traffic enters the switch.
IP Options	In an IPv4 packet, optional, these are extra fields in the packet header.
IP-precedence bits	The upper three bits in the Type of Service (ToS) field of an IP packet.
IPv4	Version 4 of the IP protocol.
outbound packet	A packet leaving the switch through any LAN port.
outbound port	Any port on the switch through which traffic leaves the switch.

Term	Use in This Document
outbound port queue	For any port, a buffer that holds outbound traffic until it can leave the switch through that port. By default, there are eight outbound queues for each port in the switch. Queue 8 is the highest priority queue; queue 1 is the lowest priority queue. Traffic in a port's high priority queue leaves the switch before any traffic in the port's medium or low priority queues.
re-marking (DSCP re-marking)	Assigns a new QoS policy to an outbound packet by changing the DSCP bit settings in the ToS byte.
tagged port membership	Identifies a port as belonging to a specific VLAN and enables VLAN-tagged packets belonging to that VLAN to carry an 802.1p priority setting when outbound from that port. Where a port is an untagged member of a VLAN, outbound packets belonging to that VLAN do not carry an 802.1p priority setting.
Type-of-Service (ToS) byte	Comprised of a three-bit (high-order) precedence field and a five-bit (low-order) Type-of-Service field. Later implementations may use this byte as a six-bit (high-order) Differentiated Services field and a two-bit (low-order) reserved field. See also "IP-precedence bits" and DSCP elsewhere in this table.
upstream device	A device linked directly or indirectly to an inbound switch port. That is, the switch <u>receives traffic from</u> upstream devices.

Overview

QoS settings operate on two levels:

- **Controlling the priority of outbound packets moving through the switch:** Each switch port has eight outbound traffic queues; the queue with a priority value of one has the lowest priority, and priority value seven has the highest priority. Packets leave the switch port on the basis of their queue assignment and whether any higher queues are empty:

Table 5-1. Port Queue Exit Priorities

Port Queue and 802.1p Priority Values	Priority for Exiting From the Port
Low (1)	Eighth
Low (2)	Seventh
Normal (0)	Sixth
Normal (3)	Fifth
Medium (4)	Fourth
Medium (5)	Third
High (6)	Second
High (7)	First

A QoS configuration enables you to set the outbound priority queue to which a packet is sent. (In an 802.1Q VLAN environment with VLAN-tagged ports, if QoS is *not* configured on the switch, but *is* configured on an upstream device, the priorities carried in the packets determine the forwarding queues in the switch.)

■ **Configuring a priority for outbound packets and a service (priority) policy for use by downstream devices:**

- **DSCP Policy:** This feature enables you to set a priority policy in outbound IP packets. (You can configure downstream devices to read and use this policy.) This method is not dependent on VLAN-tagged ports to carry priority policy to downstream devices, and can:
 - Change the codepoint (the upper six bits) in the ToS byte.
 - Set a new 802.1p priority for the packet.

(Setting DSCP policies requires IPv4 inbound packets. Refer to the “IPv4” entry under “Terminology” on page 5-6.)

- **802.1p Priority Rules:** An outbound, VLAN-tagged packet carries an 802.1p priority setting that was configured (or preserved) in the switch. This priority setting ranges from 0 to 7, and can be used by downstream devices having up to eight outbound port queues. Thus, while packets within the switch move at the eight priority levels shown in table 5-1, above, they still can carry an 802.1p priority that can be used by downstream devices having more or less than the eight priority levels in the switches covered in this guide. Also, if the packet enters the switch with an 802.1p priority setting, QoS can override this setting if configured with an 802.1p priority rule to do so.

Notes

If your network uses only one VLAN (and therefore does not require VLAN-tagged ports) you can still preserve 802.1p priority settings in your traffic by configuring the ports as tagged VLAN members on the links between devices you want to honor traffic priorities.

You can configure a QoS priority of 0 through 7 for an outbound packet. When the packet is then sent to a port, the QoS priority determines which outbound queue the packet uses:

Table 5-2. QoS Priority Settings and Operation

QoS Priority Setting	Outbound Port Queue
1 - 2	low priority (1, 2)
0 - 3	normal priority (3, 4)
4 - 5	medium priority (5, 6)
6 - 7	high priority (7, 8)

If a packet is not in a VLAN-tagged port environment, then the QoS settings in table 5-2 control only to which outbound queue the packet goes. Without VLAN tagging, no 802.1p priority is added to the packet for downstream device use. But if the packet is in a VLAN-tagged environment, then the above setting is also added to the packet as an 802.1p priority for use by downstream devices and applications (shown in table 5-3). In either case, an IP packet can also carry a priority policy to downstream devices by using DSCP-marking in the ToS byte.

Table 5-3. Mapping Switch QoS Priority Settings to Device Queues

Priority Setting	Outbound Port Queues in the Switch	802.1p Priority Setting Added to Tagged VLAN Packets Leaving the Switch	Queue Assignment in Downstream Devices With:		
			8 Queues	3 Queues	2 Queues
1	Queue 1	1 (low priority)	Queue 1	Queue 1	Queue 1
2	Queue 2	2	Queue 2	Queue 2	
0	Queue 3	0 (normal priority)	Queue 3		
3	Queue 4	3	Queue 4	Queue 3	Queue 2
4	Queue 5	4 (medium priority)	Queue 5		
5	Queue 6	5	Queue 6		
6	Queue 7	6 (high priority)	Queue 7		
7	Queue 8	7	Queue 8		

Note

The QoS queue configuration feature can change the number of outbound port queues in the switch from eight to four queues (the default) or two queues. For more information, see “QoS Queue Configuration” on page 5-62.

**Note On Using
Multiple
Criteria**

Classifiers for Prioritizing Outbound Packets

ProCurve recommends that you configure a minimum number of the available QoS classifiers for prioritizing any given packet type. Increasing the number of active classifier options for a packet type increases the complexity of the possible outcomes and consumes switch resources.

Packet Classifiers and Evaluation Order

The switches covered in this guide provide seven QoS classifiers (packet criteria) you can use to configure QoS priority.

Table 5-4. Classifier Search Order and Precedence

Search Order	Precedence	QoS Classifier Type
1	1 (highest)	UDP/TCP Application Type (port)
2	2	Device Priority (destination or source IP address)
3	3	IP Type of Service (ToS) field (IP packets only)
4	4	Protocol Priority (IP, IPX, ARP, AppleTalk, SNA, and NetBeui)
5	5	VLAN Priority
6	6	Incoming source-port on the switch
7	7 (lowest)	Incoming 802.1p Priority (present in tagged VLAN environments)

Where multiple classifier types are configured, a switch uses the highest-to-lowest search order shown in table 5-4 to identify the highest-precedence classifier to apply to any given packet. When a match between a packet and a classifier is found, the switch applies the QoS policy configured for that classifier and the packet is handled accordingly.

Note that on the switches covered in this guide, if the switch is configured with multiple classifiers that address the same packet, the switch uses only the QoS configuration for the QoS classifier that has the highest precedence. In this case, the QoS configuration for another, lower-precedence classifier that may apply is ignored. For example, if QoS assigns high priority to packets belonging to VLAN 100, but normal priority to all IP protocol packets, since protocol priority (4) has precedence over VLAN priority (5), IP protocol packets on VLAN 100 will be set to normal priority.

Preparation for Configuring QoS

Preserving 802.1p Priority

QoS operates in VLAN-tagged and VLAN-untagged environments. If your network does not use multiple VLANs, you can still implement the 802.1Q VLAN capability for packets to carry their 802.1p priority to the next downstream device. To do so, configure ports as VLAN-tagged members on the links between switches and routers in your network infrastructure.

Table 5-5. Summary of QoS Capabilities

Outbound Packet Options	Port Membership in VLANs	
	Tagged	Untagged
Control Port Queue Priority for Packet Types	Yes	Yes
Carry 802.1p Priority Assignment to Next Downstream Device	Yes	No
Carry DSCP Policy to Downstream Devices. The policy includes: Assigning a ToS Codepoint Assigning an 802.1p Priority ² to the Codepoint	Yes ¹	Yes ¹

¹ Except for non-IPv4 packets or packets processed using either the Layer 3 Protocol or QoS IP-Precedence methods, which do not include the DSCP policy option. Also, to use a service policy in this manner, the downstream devices must be configured to interpret and use the DSCP carried in the IP packets.

² This priority corresponds to the 802.1p priority scheme and is used to determine the packet's port queue priority. When used in a VLAN-tagged environment, this priority is also assigned as the 802.1p priority carried outbound in packets having an 802.1Q field in the header.

Steps for Configuring QoS on the Switch

1. Determine the QoS policy you want to implement. This includes analyzing the types of traffic flowing through your network and identifying one or more traffic types to prioritize. In order of QoS precedence, these are:
 - a. UDP/TCP applications
 - b. Device Priority—destination or source IP address (Note that destination has precedence over source. See Table 5-6.)
 - c. IP Type-of-Service Precedence Bits (Leftmost three bits in the ToS field of IP packets)
 - d. IP Type-of-Service Differentiated Service bits (Leftmost six bits in the ToS field of IP packets)
 - e. Protocol Priority

- f. VLAN Priority (requires at least one tagged VLAN on the network)
 - g. Source-Port
 - h. Incoming 802.1p Priority (requires at least one tagged VLAN on the network)
2. Select the QoS option you want to use. Table 5-6 lists the traffic types (QoS classifiers) and the QoS options you can use for prioritizing or setting a policy on these traffic types:

Table 5-6. Applying QoS Options to Traffic Types Defined by QoS Classifiers

QoS Options for Prioritizing Outbound Traffic		QoS Classifiers						
		UDP/ TCP	IP Device	IP-ToS Precedence	IP- DiffServ	L3 Protocol	VLAN -ID	Source -Port
Option 1: Configure 802.1p Priority Rules Only	Prioritize traffic by sending specific packet types (determined by QoS classifier) to different outbound port queues on the switch. Rely on VLAN-tagged ports to carry packet priority as an 802.1p value to downstream devices.	Yes	Yes	Yes ¹	Yes	Yes	Yes	Yes
Option 2: Configure ToS DSCP Policies with 802.1p Priorities	Prioritize traffic by sending specific packet types (determined by QoS classifier) to different outbound port queues on the switch. Propagate a service policy by reconfiguring the DSCP in outbound IP packets according to packet type. The packet is placed in an outbound port queue according to the 802.1p priority configured for that DSCP policy. (The policy assumes that downstream devices can be configured to recognize the DSCP in IP packets and implement the service policy it indicates.) Use VLAN-tagged ports to include packet priority as an 802.1p value to downstream devices.	Yes	Yes	No	Yes	No	Yes	Yes

¹ In this mode the configuration is fixed. You cannot change the automatic priority assignment when using IP-ToS Precedence as a QoS classifier.

3. If you want 802.1p priority settings to be included in outbound packets, ensure that tagged VLANs are configured on the appropriate downstream links.

4. Determine the actual QoS configuration changes you will need to make on each QoS-capable device in your network in order to implement the desired policy. Also, if you want downstream devices to read and use DSCPs in IP packets from the switch, configure them to do so by enabling ToS Differentiated Service mode and making sure the same DSCP policies are configured.

Viewing the QoS Configuration

The following show commands are available on the switches covered in this guide. Examples of the **show qos** output are included with the example for each priority type.

Syntax: show qos < priority-classifier >

tcp-udp-port-priority

Displays the current TCP/UDP port priority configuration. Refer to figure 5-7 on page 5-22.

device-priority

Displays the current device (IP address) priority configuration. Refer to figure 5-8 on page 5-25.

type-of-service

Displays the current type-of-service priority configuration. The display output differs according to the ToS option used:

- *IP Precedence: Refer to figure 5-12 on page 5-30.*
- *Diffserve: Refer to figure 5-14 on page 5-34.*

protocol-priority

Displays the current protocol priority configuration.

vlan-priority

Displays the current VLAN priority configuration. Refer to figure 5-22 on page 5-45.

port-priority

Displays the current source-port priority configuration. Refer to figure 5-27 on page 5-50.

No Override

By default, the IP ToS, Protocol, VLAN-ID, and (source) port **show** outputs automatically list **No-override** for priority options that have not been configured. This means that if you do not configure a priority for a specific option,

QoS does not prioritize packets to which that option applies, resulting in the **No override** state. In this case, IP packets received through a VLAN-tagged port receive whatever 802.1p priority they carry in the 802.1Q tag in the packet's header. VLAN-Tagged packets received through an untagged port are handled in the switch with "normal" priority. For example, figure 5-3 below shows a qos VLAN priority output in a switch where non-default priorities exist for VLANs 22 and 33, while VLAN 1 remains in the default configuration.

ProCurve(config)# show qos vlan-priority					This output shows that VLAN 1 is in the default state, while VLANs 22 and 33 have been configured for 802.1p and DSCP Policy priorities respectively.
VLAN priorities					
VLAN ID	Apply rule		DSCP	Priority	
-----	-----	+	-----	-----	
1	No-override			No-override	
22	Priority			0	
33	DSCP		000010	6	

Figure 5-3. Example of the Show QoS Output for VLAN Priority

Using QoS Classifiers to Configure Quality of Service for Outbound Traffic

QoS Feature	Default	Reference
UDP/TCP Priority	Disabled	page 5-15
IP-Device Priority	Disabled	page 5-23
IP Type-of-Service Priority	Disabled	page 5-29
VLAN-ID Priority	Disabled	page 5-43
Source-Port Priority	Disabled	page 5-49

Note

In addition to the information in this section on the various QoS classifiers, refer to “QoS Operating Notes and Restrictions” on page 5-66.

QoS UDP/TCP Priority

QoS Classifier Precedence: 1

When you use UDP or TCP and a layer 4 Application port number as a QoS classifier, traffic carrying the specified UDP/TCP port number(s) is marked with the UDP/TCP classifier’s configured priority level, without regard for any other QoS classifiers in the switch. You can have up to 50 UDP/TCP application port numbers as QoS classifiers.

Note

UDP/TCP QoS applications are supported for IPv4 packets only. For more information on packet-type restrictions, refer to “Details of Packet Criteria and Restrictions for QoS Support” on page 5-66.

Options for Assigning Priority. Priority control options for TCP or UDP packets carrying a specified TCP or UDP port number include:

- 802.1p priority
- DSCP policy (Assigning a new DSCP and an associated 802.1p priority; inbound packets must be IPv4.)

For a given TCP or UDP port number, you can use only one of the above options at a time. However, for different port numbers, you can use different options.

TCP/UDP Port Number Ranges. There are three ranges:

- Well-Known Ports: 0 - 1023
- Registered Ports: 1024 - 49151
- Dynamic and/or Private Ports: 49152 - 65535

For more information, including a listing of UDP/TCP port numbers, go to the *Internet Assigned Numbers Authority* (IANA) website at:

www.iana.org

Then click on:

Protocol Number Assignment Services

P (Under “Directory of General Assigned Numbers” heading)

Port Numbers

Assigning an 802.1p Priority Based on TCP or UDP Port Number or Range of Port Numbers

This option assigns an 802.1p priority to (IPv4) TCP or UDP packets as described below.

Syntax: qos < udp-port | tcp-port > < tcp or udp port number > priority < 0 - 7 >

Configures an 802.1p priority for outbound packets having the specified TCP or UDP application port number. This priority determines the packet's queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device.

A port range can be from 1 to 65535 (inclusive) ports or any subset thereof. See “Operating Notes on Using Port Ranges” below. The minimum port number must precede the maximum port number in the range.

(Default: Disabled)

*The **no** form of the command deletes the specified UDP or TCP port number or range of port numbers as a QoS classifier.*

Note: *If you have specified a range of port numbers, you must specify the entire range in the **no** command; you cannot remove part of a range.*

show qos tcp-udp-port-priority

Displays a listing of all TCP and UDP QoS classifiers currently in the running-config file.

Operating Notes on Using Port Ranges

- You can only have 6 concurrent policies when using unique ranges.
- You cannot have ranges that include any port numbers that have been configured as part of another QoS application port number policy.
- An error message is generated if there are not enough hardware resources available when configuring a policy.
- You must specify the entire range of configured port numbers when using the **no** form of the command, for example:

```
ProCurve(config)# qos udp-port range 1300 1399  
                    dscp 001110
```

```
ProCurve(config)# no qos range 1300 1399
```

The following example shows the 802.1p priority for the UDP and TCP port prioritization:

TCP/UDP Port	802.1p Priority for TCP	802.1p Priority for UDP
TCP Port 23 (Telnet)	7	7
UDP Port 23 (Telnet)	7	7
TCP Port 80 (World Wide Web HTTP)	2	2
UDP Port 80 (World Wide Web HTTP)	1	1

Figure 5-4. Example of Configuring and Listing 802.1p Priority Assignments on TCP/UDP Ports

Assigning a DSCP Policy Based on TCP or UDP Port Number or Range of Port Numbers

Note

The switches covered in this guide do not support DSCP policies on IPv4 packets with IP options. For more information on packet-type restrictions, refer to “Details of Packet Criteria and Restrictions for QoS Support” on page 5-66.

This option assigns a previously configured DSCP policy (codepoint and 802.1p priority) to (IPv4) TCP or UDP packets having the specified port number or range of port numbers. That is, the switch:

1. Selects an incoming IP packet if the TCP or UDP port number it carries matches the port number specified in the TCP or UDP classifier (as shown in figure 5-4, above).
2. Overwrites (re-marks) the packet’s DSCP with the DSCP configured in the switch for such packets.

3. Assigns the 802.1p priority configured in the switch for the new DSCP. (Refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 5-55.)
4. Forwards the packet through the appropriate outbound port queue.

For more on DSCP, refer to “Terminology” on page 5-6.

Steps for Creating a DSCP Policy Based on TCP/UDP Port Number Classifiers. This procedure creates a DSCP policy for IPv4 packets carrying the selected UDP or TCP port-number classifier.

1. Identify the TCP or UDP port-number classifier you want to use for assigning a DSCP policy.
2. Determine the DSCP policy for packets carrying the selected TCP or UDP port number or range of port numbers.
 - a. Determine the DSCP you want to assign to the selected packets. (This codepoint will be used to overwrite (re-mark) the DSCP carried in packets received from upstream devices.)
 - b. Determine the 802.1p priority you want to assign to the DSCP.
3. Configure the DSCP policy by using **qos dscp-map** to configure the priority to the codepoint you selected in step 2a. (For details, refer to the example later in this section, and to “Differentiated Services Codepoint (DSCP) Mapping” on page 5-55.)

Note

A codepoint must have an 802.1p priority assignment (0 - 7) before you can configure a policy for prioritizing packets by TCP or UDP port numbers or a range of port numbers. If a codepoint you want to use shows **No-override** in the **Priority** column of the DSCP map (**show qos dscp-map**), then you must assign a 0 - 7 priority before proceeding.

4. Configure the switch to assign the DSCP policy to packets with the specified TCP or UDP port number or range of port numbers.

Syntax: [no] qos <udp-port | tcp-port> <1-65535> [dscp <codepoint> | priority <0 - 7>]

*This command is optional if a priority has already been assigned to the <codepoint>. The command creates a DSCP policy by assigning an 802.1p priority to a specific DSCP. When the switch applies this policy to a packet, the priority determines the packet's queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. For IPv4 packets, the DSCP will be replaced by the codepoint specified in this command. (Default: **No-override** for most codepoints. See table 5-9 on page 5-56.)*

Syntax: [no] qos <udp-port | tcp-port> <portnum | range <start><end>>> <priority <0-7> | dscp <codepoint>>

*Assigns a DSCP policy to outbound packets having the specified TCP or UDP application port number and overwrites the DSCP in these packets with the assigned <codepoint> value. This policy includes an 802.1p priority and determines the packet's queue in the outbound port to which it is sent. (The <codepoint> must be configured with an 802.1p setting. See step 3 on page 5-19.) If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. (Default: **No-override**)*

A port range can be from 1 to 65535 (inclusive) ports or any subset thereof. See "Operating Notes on Using Port Ranges" on page 5-17. The minimum port number must precede the maximum port number in the range.

*The **no** form of the command deletes the specified UDP or TCP port number or range of port numbers as a QoS classifier.*

Note: *If you have specified a range of port numbers, you must specify the entire range in the **no** command; you cannot remove part of a range.*

show qos tcp-udp-port-priority

Displays a listing of all TCP and UDP QoS classifiers currently in the running-config file.

For example, suppose you wanted to assign these DSCP policies to the packets identified by the indicated UDP and TDP port applications:

Port Applications	DSCP Policies	
	DSCP	Priority
23-UDP	000111	7
80-TCP	000101	5
914-TCP	000010	1
1001-UDP	000010	1

1. Determine whether the DSCPs already have priority assignments, which could indicate use by existing applications. (Also, a DSCP must have a priority configured before you can assign any QoS classifiers to use it.)

Figure 5-5. Display the Current DSCP-Map Configuration

2. Configure the DSCP policies for the codepoints you want to use.

```
ProCurve(config)# qos dscp-map 000111 priority 7
ProCurve(config)# qos dscp-map 000101 priority 5
ProCurve(config)# qos dscp-map 000010 priority 1
ProCurve(config)# show qos dscp-map

DSCP -> 802.p priority mappings
DSCP policy 802.1p tag Policy name
-----
```

000000	No-override
000001	No-override
000010	1
000011	No-override
000100	No-override
000101	5
000110	No-override
000111	7
001000	No-override
:	:

DSCP Policies Configured in this Step

Figure 5-6. Assign Priorities to the Selected DSCPs

3. Assign the DSCP policies to the selected UDP/TCP port applications and display the result.

```
ProCurve(config)# qos udp-port 23 dscp 000111
ProCurve(config)# qos tcp-port 80 dscp 000101
ProCurve(config)# qos tcp-port 914 dscp 000010
ProCurve(config)# qos udp-port range 1001 2000 dscp 000010

ProCurve(config)# show qos tcp-udp-port-priority

TCP/UDP port based priorities
```

Protocol	Application Port	Apply rule	DSCP	Priority
UDP	23	DSCP	000111	7
TCP	80	DSCP	000101	5
TCP	914	DSCP	000010	1
UDP	1001-2000	DSCP	000010	1

Figure 5-7. The Completed DSCP Policy Configuration for the Specified UDP/TCP Port Applications

The switch will now apply the DSCP policies in figure 5-7 to IPV4 packets received in the switch with the specified UDP/TCP port applications. This means the switch will:

- Overwrite the original DSCPs in the selected packets with the new DSCPs specified in the above policies.
- Assign the 802.1p priorities in the above policies to the selected packets.

QoS IP-Device Priority

QoS Classifier Precedence: 2

The IP device option, which applies only to IPv4 packets, enables you to use up to 300 IP addresses (source or destination) as QoS classifiers.

Where a particular device-IP address classifier has the highest precedence in the switch for traffic addressed to or from that device, then traffic received on the switch with that address is marked with the IP address classifier's configured priority level. Different IP device classifiers can have differing priority levels.

Note

The switch does not allow a QoS IP-device priority for the Management VLAN IP address, if configured. If there is no Management VLAN configured, then the switch does not allow configuring a QoS IP-device priority for the Default VLAN IP address.

Ip address QoS does not support layer-2 SAP encapsulation. For more information on packet-type restrictions, refer to table 5-13, "Details of Packet Criteria and Restrictions for QoS Support" on page 5-66.

Options for Assigning Priority. Priority control options for packets carrying a specified IP address include:

- 802.1p priority
- DSCP policy (Assigning a new DSCP and an 802.1p priority; inbound packets must be IPv4.)

(For operation when other QoS classifiers apply to the same traffic, refer to "Classifiers for Prioritizing Outbound Packets" on page 5-10.)

For a given IP address, you can use only one of the above options at a time. However, for different IP addresses, you can use different options.

Assigning a Priority Based on IP Address

This option assigns an 802.1p priority to all IPv4 packets having the specified IP address as either a source or destination. (If both match, the priority for the IP destination address has precedence.)

Syntax: qos device-priority < ip-address > priority < 0 - 7 >

Configures an 802.1p priority for outbound packets having the specified IP address. This priority determines the packet's queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. (Default: Disabled)

no qos device-priority < ip-address >

*Removes the specified IP device-priority QoS classifier and resets the priority for that VLAN to **No-override**.*

show qos device-priority

Displays a listing of all IP device-priority QoS classifiers currently in the running-config file.

For example, configure and list the 802.1p priority for packets carrying the following IP addresses:

IP Address	802.1p Priority
10.28.31.1	7
10.28.31.130	5
10.28.31.100	1
10.28.31.101	1

```
ProCurve(config)# qos device-priority 10.28.31.1 priority 7
ProCurve(config)# qos device-priority 10.28.31.130 priority 5
ProCurve(config)# qos device-priority 10.28.31.100 priority 1
ProCurve(config)# qos device-priority 10.28.31.101 priority 1

ProCurve(config)# show qos device-priority
Device priorities
Device Address Apply rule | DSCP Priority
-----+-----
10.28.31.1 Priority | 7
10.28.31.130 Priority | 5
10.28.31.100 Priority | 1
10.28.31.101 Priority | 1
```

Figure 5-8. Example of Configuring and Listing 802.1p Priority Assignments for Packets Carrying Specific IP Addresses

Assigning a DSCP Policy Based on IP Address

Note

On the switches covered in this guide, DSCP policies cannot be applied to IPv4 packets having IP options. For more information on packet criteria and restrictions, refer to table 5-13 on page 5-66.

This option assigns a previously configured DSCP policy (codepoint and 802.1p priority) to outbound IP packets having the specified IP address (either source or destination). That is, the switch:

1. Selects an incoming IPv4 packet on the basis of the source or destination IP address it carries.
2. Overwrites the packet's DSCP with the DSCP configured in the switch for such packets, and assigns the 802.1p priority configured in the switch for the new DSCP. (Refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 5-55.)
3. Forwards the packet through the appropriate outbound port queue.

For more on DSCP, refer to “Terminology” on page 5-6.

Steps for Creating a Policy Based on IP Address. This procedure creates a DSCP policy for IPv4 packets carrying the selected IP address (source or destination).

1. Identify the IP address to use as a classifier for assigning a DSCP policy.
2. Determine the DSCP policy for packets carrying the selected IP address:

- a. Determine the DSCP you want to assign to the selected packets. (This codepoint will be used to overwrite the DSCP carried in packets received from upstream devices.)
- b. Determine the 802.1p priority you want to assign to the DSCP.
3. Configure the DSCP policy by using **dscp-map** to configure the priority to the codepoint you selected in step 2a. (For details, refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 5-55.)

Notes

A codepoint must have an 802.1p priority assignment (0 - 7) before you can configure a policy for prioritizing packets by IP address. If a codepoint you want to use shows **No-override** in the **Priority** column of the DSCP map (**show qos dscp-map**), then you must assign a 0 - 7 priority before proceeding.

On the switches covered in this guide, DSCP policies cannot be applied to IPv4 packets having IP options. For more information on packet criteria and restrictions, refer to 5-13 on page 5-66.

-
4. Configure the switch to assign the DSCP policy to packets with the specified IP address.

Syntax: `qos dscp-map < codepoint > priority < 0 - 7 >`

*This command is optional if a priority is already assigned to the < codepoint >. The command creates a DSCP policy by assigning an 802.1p priority to a specific DSCP. When the switch applies this policy to a packet, the priority determines the packet's queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. If the packet is IPv4, the packet's DSCP will be replaced by the codepoint specified in this command. (Default: For most codepoints, **No-override**. See figure 5-9 on page 5-56.)*

Syntax: `qos device-priority < ip-address > dscp < codepoint >`

*Assigns a DSCP policy to packets carrying the specified IP address, and overwrites the DSCP in these packets with the assigned < codepoint > value. This policy includes an 802.1p priority and determines the packet's queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. (Default: **No-override**)*

`no qos device-priority < ip-address >`

Deletes the specified IP address as a QoS classifier.

show qos device-priority

Displays a listing of all QoS Device Priority classifiers currently in the running-config file.

For example, suppose you wanted to assign these DSCP policies to the packets identified by the indicated IP addresses:

IP Address	DSCP Policies	
	DSCP	Priority
10.28.31.1	000111	7
10.28.31.130	000101	5
10.28.31.100	000010	1
10.28.31.101	000010	1

1. Determine whether the DSCPs already have priority assignments, which could indicate use by existing applications. This is not a problem if the configured priorities are acceptable for all applications using the same DSCP. (Refer to the “Notes on Changing a Priority Setting” on page 5-58. Also, a DSCP must have a priority configured before you can assign any QoS classifiers to use it.)

```
ProCurve(config)# show qos dscp-map
DSCP -> 802.p priority mappings
DSCP policy 802.1p tag Policy name
-----
000000 No-override
000001 No-override
000010 No-override
000011 No-override
000100 No-override
000101 No-override
000110 No-override
000111 No-override
:
```

The DSCPs for this example have not yet been assigned an 802.1p priority level.

Figure 5-9. Display the Current DSCP-Map Configuration

2. Configure the priorities for the DSCPs you want to use.

```
ProCurve(config)# qos dscp-map 000111 priority 7
ProCurve(config)# qos dscp-map 000101 priority 5
ProCurve(config)# qos dscp-map 000010 priority 1
ProCurve(config)# show qos dscp-map
```

DSCP -> 802.p priority mappings

DSCP Policies Configured in this step.

Figure 5-10. Assigning 802.1p Priorities to the Selected DSCPs

3. Assign the DSCP policies to the selected device IP addresses and display the result.

```
ProCurve(config)# qos device-priority 10.28.31.1 dscp 000111
ProCurve(config)# qos device-priority 10.28.31.130 dscp 000101
ProCurve(config)# qos device-priority 10.28.31.100 dscp 000010
ProCurve(config)# qos device-priority 10.28.31.101 dscp 000010
ProCurve(config)# show qos device-priority
```

Device priorities

Device Address	Apply rule	DSCP	Priority
10.28.31.1	DSCP	000111	7
10.28.31.130	DSCP	000101	5
10.28.31.100	DSCP	000010	1
10.28.31.101	DSCP	000010	1

Figure 5-11. The Completed Device-Priority/Codepoint Configuration

The switch will now apply the DSCP policies in figure 5-10 to IPv4 packets received on the switch with the specified IP addresses (source or destination). This means the switch will:

- Overwrite the original DSCPs in the selected packets with the new DSCPs specified in the above policies.
- Assign the 802.1p priorities in the above policies to the appropriate packets.

QoS IP Type-of-Service (ToS) Policy and Priority

QoS Classifier Precedence: 3

This feature applies only to IPv4 traffic and performs either of the following:

- **ToS IP-Precedence Mode:** All IP packets generated by upstream devices and applications include precedence bits in the ToS byte. Using this mode, the switch uses these bits to compute and assign the corresponding 802.1p priority.
- **ToS Differentiated Services (Diffserv) Mode:** This mode requires knowledge of the codepoints set in IP packets by the upstream devices and applications. It uses the ToS codepoint in IP packets coming from upstream devices and applications to assign 802.1p priorities to the packets. You can use this option to do both of the following:
 - **Assign a New Prioritization Policy:** A “policy” includes both a codepoint and a corresponding 802.1p priority. This option selects an incoming IPv4 packet on the basis of its codepoint and assigns a new codepoint and corresponding 802.1p priority. (Use the **qos dscp-map** command to specify a priority for any codepoint—page 5-55.)
 - **Assign an 802.1p Priority:** This option reads the DSCP of an incoming IPv4 packet and, without changing this codepoint, assigns the 802.1p priority to the packet, as configured in the DSCP Policy Table (page 5-55). This means that a priority value of 0 - 7 must be configured for a DSCP before the switch will attempt to perform a QoS match on the packet's DSCP bits.

Before configuring the ToS Diffserv mode, you must use the **dscp-map** command to configure the desired 802.1p priorities for the codepoints you want to use for either option. This command is illustrated in the following examples and is described under “Differentiated Services Codepoint (DSCP) Mapping” on page 5-55.

Unless IP-Precedence mode and Diffserv mode are both disabled (the default setting), enabling one automatically disables the other. For more on ToS operation, refer to “Details of QoS IP Type-of-Service” on page 5-38.

Assigning an 802.1p Priority to IPv4 Packets on the Basis of the ToS Precedence Bits

If a device or application upstream of the switch sets the precedence bits in the ToS byte of IPv4 packets, you can use this feature to apply that setting for prioritizing packets for outbound port queues. If the outbound packets are in a tagged VLAN, this priority is carried as an 802.1p value to the adjacent downstream devices.

Syntax: qos type-of-service ip-precedence

Causes the switch to automatically assign an 802.1p priority to all IPv4 packets by computing each packet's 802.1p priority from the precedence bits the packet carries. This priority determines the packet's queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. (ToS IP Precedence Default: Disabled)

no qos type-of-service

Disables all ToS classifier operation, including prioritization using the precedence bits.

show qos type-of-service

When ip-precedence is enabled (or if neither ToS option is configured), shows the ToS configuration status. If diff-services is enabled, lists codepoint data as described under "Assigning a DSCP Policy on the Basis of the DSCP in IPv4 Packets Received from Upstream Devices" on page 5-35.

With this option, prioritization of outbound packets relies on the IP-Precedence bit setting that IP packets carry with them from upstream devices and applications. To configure and verify this option:

Figure 5-12. Example of Enabling ToS IP-Precedence Prioritization

To replace this option with the ToS diff-services option, configure **diff-services** as described below, which automatically disables IP-Precedence. To disable IP-Precedence without enabling the diff-services option, use this command:

```
ProCurve(config)# no qos type-of-service
```

Assigning an 802.1p Priority to IPv4 Packets on the Basis of Incoming DSCP

One of the best uses for this option is on an interior switch where you want to honor (continue) a policy set on an edge switch. That is, it enables you to select incoming packets having a specific DSCP and forward these packets with the desired 802.1p priority. For example, if an edge switch “A” marks all packets received on port A5 with a particular DSCP, you can configure a downstream (interior) switch “B” to handle such packets with the desired priority (regardless of whether 802.1Q tagged VLANs are in use).

Figure 5-13. Interior Switch “B” Honors the Policy Established in Edge Switch “A”

To do so, assign the desired 802.1p priority to the same codepoint that the upstream or edge switch assigns to the selected packets. When the downstream switch receives an IPv4 packet carrying one of these codepoints, it assigns the configured priority to the packet and sends it out the appropriate priority queue. (The packet retains the codepoint it received from the upstream or edge switch). You can use this option concurrently with the diffserv DSCP Policy option (described later in this section), as long as the DSCPs specified in the two options do not match.

Operating Notes

Different applications may use the same DSCP in their IP packets. Also, the same application may use multiple DSCPs if the application originates on different clients, servers, or other devices. Using an edge switch enables you to select the packets you want and mark them with predictable DSCPs that can be used by downstream switches to honor policies set in the edge switch.

When enabled, the switch applies direct 802.1p prioritization to all packets having codepoints that meet these criteria:

- The codepoint is configured with an 802.1p priority in the DSCP table. (Codepoints configured with **No-override** are not used.)
- The codepoint is not configured for a new DSCP policy assignment.

Thus, the switch does not allow the same incoming codepoint (DSCP) to be used simultaneously for directly assigning an 802.1p priority and also assigning a DSCP policy. For a given incoming codepoint, if you configure one option and then the other, the second overwrites the first.

To use this option:

1. Identify a DSCP used to set a policy in packets received from an upstream or edge switch.
2. Determine the 802.1p priority (0 - 7) you want to apply to packets carrying the identified DSCP. (You can either maintain the priority assigned in the upstream or edge switch, or assign a new priority.)
3. Use **qos dscp-map <codepoint> priority <0 - 7>** to assign the 802.1p priority you want to the specified DSCP. (For more on this topic, refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 5-55.)
4. Enable **diff-services**

Syntax: qos type-of-service diff-services < codepoint >

Causes the switch to read the < codepoint > (DSCP) of an incoming IPv4 packet and, when a match occurs, assign a corresponding 802.1p priority, as configured in the switch's DSCP table (page 5-56).

no qos type-of-service

Disables all ToS classifier operation.

no qos dscp-map < codepoint >

*Disables direct 802.1p priority assignment to packets carrying the < codepoint > by reconfiguring the codepoint priority assignment in the DSCP table to **No-override**. Note that if this codepoint is in use as a DSCP policy for another diffserv codepoint, you must disable or redirect the other diffserv codepoint's DSCP policy before you can disable or change the codepoint. For example, in figure 5-14 you cannot change the priority for the 000000 codepoint until you redirect the DSCP policy for 000001 away from using 000000 as a policy. (Refer to "Notes on Changing a Priority Setting" on page 5-58. Refer also to "Differentiated Services Codepoint (DSCP) Mapping" on page 5-55.)*

show qos type-of-service

Displays current Type-of-Service configuration. In diffserv mode it also shows the current direct 802.1p assignments and the current DSCP assignments covered later in this section.

For example, an edge switch "A" in an untagged VLAN assigns a DSCP of 000110 on IP packets it receives on port A6, and handles the packets with high priority (7). When these packets reach interior switch "B" you want the switch to handle them with the same high priority. To enable this operation you would

Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers to Configure Quality of Service for Outbound Traffic

configure an 802.1p priority of 7 for packets received with a DSCP of **000110**, and then enable **diff-services**:

```
ProCurve(config)# show qos type-of-service
Type of Service [Disabled] : Disabled
```

Codepoint	DSCP Policy	Priority
000000		1
000001	000000	1
000010		No-override
000011		No-override
000100	001001	5
000101		No-override
000110		No-override
000111		No-override
001000		No-override
001001		5
001010		1
001011		No-override
.	.	.
.	.	.
.	.	.

Executing this command displays the current ToS configuration and shows that the selected DSCP is not currently in use.

The **000110** codepoint is unused, and thus available for directly assigning an 802.1p priority without changing the packet's DSCP.

Note: All codepoints without a "DSCP Policy" entry are available for direct 802.1p priority assignment.

Figure 5-14. Example Showing Codepoints Available for Direct 802.1p Priority Assignments

```
ProCurve(config)# qos dscp-map 000110 priority 7
ProCurve(config)# qos type-of-service diff-services
ProCurve(config)# show qos type-of-service
Type of Service [Disabled] : Differentiated Services
```

Codepoint	DSCP Policy	Priority
000000		1
000001	000000	1
000010		No-override
000011		No-override
000100	001001	5
000101		No-override
000110		7
000111		No-override
001000		No-override
001001		5
.	.	.
.	.	.
.	.	.

Outbound IP packets with a DSCP of **000110** will have a priority of 7.

Notice that codepoints **000000** and **001001** are named as DSCP policies by other codepoints (**000001** and **000110** respectively). This means they are not available for changing to a different 802.1p priority.

Figure 5-15. Example of a Type-of-Service Configuration Enabling Both Direct 802.1p Priority Assignment and DSCP Policy Assignment

Assigning a DSCP Policy on the Basis of the DSCP in IPv4 Packets Received from Upstream Devices

The preceding section describes how to forward a policy set by an edge (or upstream) switch. This option changes a DSCP policy in an IPv4 packet by changing its IP ToS codepoint and applying the priority associated with the new codepoint. (A DSCP policy consists of a differentiated services codepoint and an associated 802.1p priority.) You can use this option concurrently with the diffserv 802.1p priority option (above), as long as the DSCPs specified in the two options do not match.

To use this option to configure a change in policy:

1. Identify a DSCP used to set a policy in packets received from an upstream or edge switch.
2. Create a new policy by using **qos dscp-map <codepoint> priority <0 - 7>** to configure an 802.1p priority for the codepoint you will use to overwrite the DSCP the packet carries from upstream. (For more on this topic, refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 5-55.)
3. Use **qos type-of-service diff-services <incoming-DSCP> dscp <outgoing-DSCP>** to change the policy on packets coming from the edge or upstream switch with the specified incoming DSCP.

(Figure 5-13 on page 5-31 illustrates this scenario.)

Note

On the switches covered in this guide, DSCP policies (codepoint re-marking) cannot be applied to outbound IPv4 packets having IP options. (The 802.1p priority in the VLAN tag is applied.) For more information on packet criteria and restrictions, refer to 5-13 on page 5-66.

Syntax: qos type-of-service diff-services

Enables ToS diff-services.

Syntax: qos type-of-service diff-services < current-codepoint > dscp
< new-codepoint >

*Configures the switch to select an incoming IP packet carrying the <current-codepoint> and then use the <new-codepoint> to assign a new, previously configured DSCP policy to the packet. The policy overwrites the <current-codepoint> with the < new-codepoint > and assigns the 802.1p priority specified by the policy. (Use the **qos dscp-map** command to define the priority for the DSCPs—page 5-55.)*

Syntax: no qos type-of-service

Disables all ToS classifier operation. Current ToS DSCP policies and priorities remain in the configuration and will become available if you re-enable ToS diff-services.

Syntax: no qos type-of-service [diff-services < codepoint >]

*Deletes the DSCP policy assigned to the < codepoint > and returns the < codepoint > to the 802.1p priority setting it had before the DSCP policy was assigned. (This will be either a value from 0 - 7 or **No-override**.)*

Syntax: show qos type-of-service

Displays a listing of codepoints, with any corresponding DSCP policy re-assignments for outbound packets. Also lists the (802.1p) priority for each codepoint that does not have a DSCP policy assigned to it.

For example, suppose you want to configure the following two DSCP policies for packets received with the indicated DSCPs.

Received DSCP	Policy DSCP	802.1p Priority	Policy Name (Optional)
001100	000010	6	Level 6
001101	000101	4	Level 4

1. Determine whether the DSCPs already have priority assignments, which could indicate use by existing applications. This is not a problem as long as the configured priorities are acceptable for all applications using the

same DSCP. (Refer to the “Notes on Changing a Priority Setting” on page 5-58. Also, a DSCP must have a priority configured before you can assign any QoS classifiers to use it.)

```
ProCurve(config)# show qos dscp-map
DSCP -> 802.p priority mappings
DSCP policy 802.1p tag Policy name
-----
000000      No-override
000001      No-override
000010      No-override
000011      No-override
000100      No-override
000101      No-override
000110      No-override
000111      No-override
.           .
.           .
.           .
```

The DSCPs for this example have not yet been assigned an 802.1p priority level.

Figure 5-16. Display the Current DSCP-Map Configuration

2. Configure the policies in the DSCP table:

```
ProCurve(config)# qos dscp-map 000010 priority 6 name 'Level 6'
ProCurve(config)# qos dscp-map 000101 priority 4 name 'Level 4'

ProCurve(config)# show qos dscp-map
DSCP -> 802.p priority mappings
DSCP policy 802.1p tag Policy name
-----
000000      No-override
000001      No-override
000010      6          Level 6
000011      No-override
000100      No-override
000101      4          Level 4
000110      No-override
000111      No-override
.           .           .
.           .           .
.           .           .
```

Figure 5-17. Example of Policies Configured (with Optional Names) in the DSCP Table

3. Assign the policies to the codepoints in the selected packet types.

Figure 5-18. Example of Policy Assignment to Outbound Packets on the Basis of the DSCP in the Packets Received from Upstream Devices

Details of QoS IP Type-of-Service

IP packets include a Type of Service (ToS) byte. The ToS byte includes:

- **A Differentiated Services Codepoint (DSCP):** This element is comprised of the upper six bits of the ToS byte). There are 64 possible codepoints.
 - In the switches covered in this guide, the default **qos** configuration includes some codepoints with 802.1p priority settings for Assured-Forwarding and Expedited Forwarding (codepoint 101110), while others are unused (and listed with **No-override** for a Priority).

Refer to figure 5-9 on page 5-56 for an illustration of the default DSCP policy table.

Using the **qos dscp map** command, you can configure the switch to assign different prioritization policies to IPv4 packets having different code-points. As an alternative, you can configure the switch to assign a new codepoint to an IPv4 packet, along with a corresponding 802.1p priority (0-7). To use this option in the simplest case, you would:

- a. Configure a specific DSCP with a specific priority in an edge switch.
- b. Configure the switch to mark a specific type of inbound traffic with that DSCP (and thus create a policy for that traffic type).
- c. Configure the internal switches in your LAN to honor the policy.

(For example, you could configure an edge switch to assign a codepoint of 000001 to all packets received from a specific VLAN, and then handle all traffic with that codepoint at high priority.)

For a codepoint listing and the commands for displaying and changing the DSCP Policy table, refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 5-55.

- **Precedence Bits:** This element is a subset of the DSCP and is comprised of the upper three bits of the ToS byte. When configured to do so, the switch uses the precedence bits to determine a priority for handling the associated packet. (The switch does not change the setting of the precedence bits.) Using the ToS Precedence bits to prioritize IPv4 packets relies on priorities set in upstream devices and applications.

Figure 5-19 shows an example of the ToS byte in the header for an IPv4 packet, and illustrates the diffserv bits and precedence bits in the ToS byte. (Note that the Precedence bits are a subset of the Differentiated Services bits.)

Figure 5-19. The ToS Codepoint and Precedence Bits

Table 5-7. How the Switch Uses the ToS Configuration

Outbound Port	ToS Option:	
	802.1p (Value = 0 - 7)	Differentiated Services
IP Packet Sent Out an Untagged Port in a VLAN	Depending on the value of the IP Precedence bits in the packet's ToS field, the packet will go to one of eight outbound port queues in the switch: 1 - 2 = low priority (queue 1, 2) 0 - 3 = normal priority (queue 3, 4) 4 - 5 = medium priority (queue 5, 6) 6 - 7 = high priority (queue 7, 8)	For a given packet carrying a ToS codepoint that the switch has been configured to detect: - Change the codepoint according to the configured policy and assign the 802.1p priority specified for the new codepoint in the DSCP Policy Table (page 5-55). - Do not change the codepoint, but assign the 802.1p priority specified for the existing codepoint in the DSCP Policy Table (page 5-55). Depending on the 802.1p priority used, the packet will leave the switch through one of the following queues: 1 - 2 = low priority (queue 1, 2) 0 - 3 = normal priority (queue 3, 4) 4 - 5 = medium priority (queue 5, 6) 6 - 7 = high priority (queue 7, 8) If No-override (the default) has been configured for a specified codepoint, then the packet is not prioritized by ToS and, by default, is sent to the "normal priority" queue.
	Same as above, plus the IP Precedence value (0 - 7) will be used to set a corresponding 802.1p priority in the VLAN tag carried by the packet to the next downstream device. Refer to table 5-8, below.	Same as above, plus the Priority value (0 - 7) will be used to set a corresponding 802.1p priority in the VLAN tag carried by the packet to the next downstream device. Where No-override is the assigned priority, the VLAN tag carries a "0" (normal priority) 802.1p setting if not prioritized by other QoS classifiers.

Table 5-8. ToS IP-Precedence Bit Mappings to 802.1p Priorities

ToS Byte IP Precedence Bits	Corresponding 802.1p Priority	Service Priority Level
000	1	Lowest
001	2	Low
002	0	Normal
003	3	
004	4	
005	5	
006	6	
007	7	Highest

QoS Protocol Priority

QoS Classifier Precedence: 4

When QoS on the switch is configured with a Layer-3 protocol as the highest-precedence classifier and the switch receives traffic carrying that protocol, then this traffic is assigned the priority configured for this classifier. (For operation when other QoS classifiers apply to the same traffic, refer to “Classifiers for Prioritizing Outbound Packets” on page 5-10.)

Assigning a Priority Based on Layer-3 Protocol

This option assigns an 802.1p priority to outbound packets having the specified Layer-3 protocol.

Syntax: qos protocol

< ip | ipx | arp | appletalk | sna | netbeui > priority < 0 - 7 >

*Configures an 802.1p priority for outbound packets having the specified protocol. This priority determines the packet's queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. You can configure one QoS classifier for each protocol type. (Default: **No-override**)*

no qos protocol

< ip | ipx | arp | appletalk | sna | netbeui >

*Disables use of the specified protocol as a QoS classifier and resets the protocol priority to **No-override**.*

show qos protocol

Lists the QoS protocol classifiers with their priority settings.

For example:

1. Configure QoS protocol classifiers with IP at 0 (normal), ARP at 5 (medium), and AppleTalk at 7 (high) and display the QoS protocol configuration.
2. Disable the QoS IP protocol classifier, downgrade the ARP priority to 4, and again display the QoS protocol configuration.

Figure 5-20 shows the command sequence and displays for the above steps.

Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers to Configure Quality of Service for Outbound Traffic

```
ProCurve(config)# qos protocol ip priority 0
ProCurve(config)# qos protocol appletalk priority 7
ProCurve(config)# qos protocol arp priority 5

ProCurve(config)# show qos protocol

  Protocol priorities

  Protocol  Priority
  -----  -
  IP        0
  IPX       No-override
  ARP       5
  AppleTalk 7
  SNA       No-override
  Net BEUI  No-override
```

ProCurve(config)# no qos protocol ip ← Removes IP as QoS classifier.
ProCurve(config)# qos protocol arp priority 4 ← Changes the priority of the ARP QoS classifier.
ProCurve(config)# show qos protocol ← Displays the results of these changes.

```
  Protocol priorities

  Protocol  Priority
  -----  -
  IP        No-override
  IPX       No-override
  ARP       4
  AppleTalk 7
  SNA       No-override
  Net BEUI  No-override
```

Figure 5-20. Adding, Displaying, Removing, and Changing QoS Protocol Classifiers

QoS VLAN-ID (VID) Priority

QoS Classifier Precedence: 5

The QoS protocol option enables you to use up to 256 VIDs as QoS classifiers. Where a particular VLAN-ID classifier has the highest precedence in the switch for traffic in that VLAN, then traffic received in that VLAN is marked with the VID classifier's configured priority level. Different VLAN-ID classifiers can have differing priority levels.

Options for Assigning Priority. Priority control options for packets carrying a specified VLAN-ID include:

- 802.1p priority
- DSCP policy (Assigning a new DSCP and an associated 802.1p priority; inbound packets must be IPv4.)

(For operation when other QoS classifiers apply to the same traffic, refer to “Classifiers for Prioritizing Outbound Packets” on page 5-10.)

Note

QoS with VID priority applies to static VLANs only, and applying QoS to dynamic VLANs created by GVRP operation is not supported. A VLAN must exist while a subject of a QoS configuration, and eliminating a VLAN from the switch causes the switch to clear any QoS features configured for that VID.

Assigning a Priority Based on VLAN-ID

This option assigns a priority to all outbound packets having the specified VLAN-ID (VID). You can configure this option by either specifying the VLAN-ID ahead of the **qos** command or moving to the VLAN context for the VLAN you want to configure for priority.

Syntax: `vlan < vid > qos priority < 0 - 7 >`

*Configures an 802.1p priority for outbound packets belonging to the specified VLAN. This priority determines the packet's queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. You can configure one QoS classifier for each VLAN-ID. (Default: **No-override**)*

Syntax: `no vlan < vid > qos`

*Removes the specified VLAN-ID as a QoS classifier and resets the priority for that VLAN to **No-override**.*

Syntax: `show qos vlan-priority`

Displays a listing of the QoS VLAN-ID classifiers currently in the running-config file, with their priority data.

1. For example, suppose that you have the following VLANs configured on the switch and want to prioritize them as shown:

ProCurve(config)# show vlan			
Status and Counters - VLAN Information			
Maximum VLANs to support : 8			
Primary VLAN : DEFAULT_VLAN			
	802.1Q	VLAN ID Name	Status
Set Priority To 2	①	DEFAULT_VLAN	Static
Set Priority To 5	②	VLAN_20	Static
Set Priority To 7	③	VLAN_30	Static
	④	VLAN_40	Static

Figure 5-21. Example of a List of VLANs Available for QoS Prioritization

2. You would then execute the following commands to prioritize the VLANs by VID:

```
ProCurve(config)# vlan 1 qos priority 2
ProCurve(config)# vlan 20 qos priority 5
ProCurve(config)# vlan 30 qos priority 5
ProCurve(config)# vlan 40 qos priority 7

ProCurve(config)# show qos vlan
```

VLAN priorities			
VLAN ID	Apply rule	DSCP	Priority
1	Priority		2
20	Priority		5
30	Priority		5
40	Priority		7

Figure 5-22. Configuring and Displaying QoS Priorities on VLANs

If you then decided to remove VLAN_20 from QoS prioritization:

```
ProCurve(config)# no vlan 20 qos
ProCurve(config)# show qos vlan
```

VLAN priorities			
VLAN ID	Apply rule	DSCP	Priority
1	Priority		2
20	No-override		No-override
30	Priority		5
40	Priority		7

In this instance, **No-override** indicates that VLAN 20 is not prioritized by QoS.

Figure 5-23. Returning a QoS-Prioritized VLAN to “No-override” Status

Assigning a DSCP Policy Based on VLAN-ID (VID)

This option assigns a previously configured DSCP policy (codepoint and 802.1p priority) to outbound IP packets having the specified VLAN-ID (VID). That is, the switch:

1. Selects an incoming IP packet on the basis of the VLAN-ID it carries.
2. Overwrites the packet’s DSCP with the DSCP configured in the switch for such packets.
3. Assigns the 802.1p priority configured in the switch for the new DSCP. (Refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 5-55.)
4. Forwards the packet through the appropriate outbound port queue.

For more on DSCP, refer to “Terminology” on page 5-6.

Steps for Creating a Policy Based on VLAN-ID Classifier.

1. Determine the VLAN-ID classifier to which you want to assign a DSCP policy.
2. Determine the DSCP policy for packets carrying the selected VLAN-ID:
 - a. Determine the DSCP you want to assign to the selected packets. (This codepoint will be used to overwrite the DSCP carried in packets received from upstream devices.)
 - b. Determine the 802.1p priority you want to assign to the DSCP.
3. Configure the DSCP policy by using **qos dscp-map** to configure the priority for each codepoint. (For details, see the example later in this section, and to “Differentiated Services Codepoint (DSCP) Mapping” on page 5-55.)

Note

A codepoint must have an 802.1p priority (0 - 7) before you can configure the codepoint for use in prioritizing packets by VLAN-ID. If a codepoint you want to use shows **No-override** in the **Priority** column of the DSCP Policy table (**show qos dscp-map**), then assign a priority before proceeding.

4. Configure the switch to assign the DSCP policy to packets with the specified VLAN-ID.

Syntax: `qos dscp-map < codepoint > priority < 0 - 7 >`

*This command is optional if a priority has already been assigned to the < codepoint >. The command creates a DSCP policy by assigning an 802.1p priority to a specific DSCP. When the switch applies this priority to a packet, the priority determines the packet's queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. If the packet is IPv4, the packet's DSCP will be replaced by the codepoint specified in this command. (Default: For most codepoints, **No-override**. See figure 5-9 on page 5-56 on page 5-56.)*

Syntax: `vlan < vid > qos dscp < codepoint >`

Assigns a DSCP policy to packets carrying the specified VLAN-ID, and overwrites the DSCP in these packets with the assigned < codepoint > value. This policy includes an 802.1p priority and determines the packet's queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. (Default: No-override)

Syntax: `no vlan < vid > qos`

Removes QoS classifier for the specified VLAN.

Syntax: `show qos device-priority`

Displays a listing of all QoS VLAN-ID classifiers currently in the running-config file.

For example, suppose you wanted to assign this set of priorities:

VLAN-ID	DSCP	Priority
40	000111	7
30	000101	5
20	000010	1
1	000010	1

1. Determine whether the DSCPs already have priority assignments, which could indicate use by existing applications. This is not a problem as long as the configured priorities are acceptable for all applications using the same DSCP. (Refer to the “Notes on Changing a Priority Setting” on page 5-58. Also, a DSCP must have a priority configured before you can assign any QoS classifiers to use it.)

```
ProCurve(config)# show qos dscp-map
DSCP -> 802.p priority mappings
DSCP policy 802.1p tag Policy name
-----
000000 No-override
000001 No-override
000010 No-override
000011 No-override
000100 No-override
000101 No-override
000110 No-override
000111 No-override
:
```

The DSCPs for this example have not yet been assigned an 802.1p priority level.

Figure 5-24. Display the Current Configuration in the DSCP Policy Table

2. Configure the priorities for the DSCPs you want to use.

```
ProCurve(config)# qos dscp-map 000111 priority 7
ProCurve(config)# qos dscp-map 000101 priority 5
ProCurve(config)# qos dscp-map 000010 priority 1
ProCurve(config)# show qos dscp-map
```

DSCP -> 802.1p priority mappings

DSCP	802.1p	priority	mappings
000000	No-override		
000001	No-override		
000010	1		
000011	No-override		
000100	No-override		
000101	5		
000110	No-override		
000111	7		
001000	No-override		
:	:		
:	:		
:	:		

Priorities Configured in this step.

Figure 5-25. Assign Priorities to the Selected DSCPs

3. Assign the DSCP policies to the selected VLANs and display the result.

```
ProCurve(config)# vlan 1 qos dscp 000010
ProCurve(config)# vlan 20 qos dscp 000010
ProCurve(config)# vlan 30 qos dscp 000101
ProCurve(config)# vlan 40 qos dscp 000111
ProCurve(config)# show qos vlan-priority
```

VLAN priorities

VLAN ID	Apply rule	DSCP	Priority
1	DSCP	000010	1
20	DSCP	000010	1
30	DSCP	000101	5
40	DSCP	000111	7

Figure 5-26. The Completed VLAN-DSCP Priority Configuration

The switch will now apply the DSCP policies in figure 5-26 to packets received on the switch with the specified VLAN-IDs. This means the switch will:

- Overwrite the original DSCPs in the selected packets with the new DSCPs specified in the above policies.
- Assign the 802.1p priorities in the above policies to the appropriate packets.

QoS Source-Port Priority

QoS Classifier Precedence: 6

The QoS source-port option enables you to use a packet's source-port on the switch as a QoS classifier. Where a particular source-port classifier has the highest precedence in the switch for traffic entering through that port, then traffic received from the port is marked with the source-port classifier's configured priority level. Different source-port classifiers can have different priority levels.

Options for Assigning Priority on the Switch. Priority control options for packets from a specified source-port include:

- 802.1p priority
- DSCP policy (Assigning a new DSCP and an associated 802.1p priority; inbound packets must be IPv4.)

(For operation when other QoS classifiers apply to the same traffic, refer to "Classifiers for Prioritizing Outbound Packets" on page 5-10.)

Options for Assigning Priority From a RADIUS Server. You can use a RADIUS server to impose a QoS source-port priority during an 802.1X port-access authentication session. Refer to the RADIUS chapter in the *Access Security Guide* for your switch.

Assigning a Priority Based on Source-Port

This option assigns a priority to all outbound packets having the specified source-port. You can configure this option by either specifying the source-port ahead of the **qos** command or moving to the port context for the port you want to configure for priority. (If you are configuring multiple source-ports with the same priority, you may find it easier to use the **interface < port-list >** command to go to the port context instead of individually configuring the priority for each port.)

Syntax: interface < port-list > qos priority < 0 - 7 >

Configures an 802.1p priority for packets entering the switch through the specified (source) ports. This priority determines the packet queue in the outbound port(s) to which traffic is sent. If a packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. You can configure one QoS classifier for each source-port or group of source-ports. (Default: No-override)

Syntax: no interface < port-list > qos

*Disables use of the specified source-port(s) for QoS classifier(s) and resets the priority for the specified source-port(s) to **No-override**.*

Syntax: show qos port-priority

Lists the QoS port-priority classifiers with their priority data.

For example, suppose that you want to prioritize inbound traffic on the following source-ports:

Source-Port	Priority
A1 - A3	2
A4	3
B1, B4	5
C1-C3	6

You would then execute the following commands to prioritize traffic received on the above ports:

```

ProCurve(config)# interface e c1-c3 qos priority 6
ProCurve(config)# interface e b1,b4 qos priority 5
ProCurve(config)# interface e a4 qos priority 3
ProCurve(config)# interface e a1-a3 qos priority 2
ProCurve(config)# show qos port-priority
  
```

Port	Apply rule	DSCP	Priority	Radius Override
A1	Priority		2	No-override
A2	Priority		2	No-override
A3	Priority		2	No-override
A4	Priority		3	No-override
B1	Priority		5	No-override
B2	No-override		No-override	No-override
B3	No-override		No-override	No-override
B4	Priority		5	No-override
C1	Priority		6	No-override
C2	Priority		6	No-override
C3	Priority		6	No-override
C4	No-override		No-override	No-override
C5	No-override		No-override	No-override
.	.		.	.
.	.		.	.

The diagram shows arrows connecting the configuration commands to the output table:

- ProCurve(config)# interface e c1-c3 qos priority 6 → C1, C2, C3
- ProCurve(config)# interface e b1,b4 qos priority 5 → B1, B4
- ProCurve(config)# interface e a4 qos priority 3 → A4
- ProCurve(config)# interface e a1-a3 qos priority 2 → A1, A2, A3

Figure 5-27. Configuring and Displaying Source-Port QoS Priorities

If you then decided to remove port A1 from QoS prioritization:

ProCurve(config)# no interface e a1 qos				
ProCurve(config)# show qos port-priority				
Port priorities				
Port	Apply rule	DSCP	Priority	Radius Override
A1	No-override		No-override	No-override
A2	Priority		2	No-override
A3	Priority		2	No-override
A4	Priority		3	No-override

In this instance, **No-override** indicates that port A1 is not prioritized by QoS.

Figure 5-28. Returning a QoS-Prioritized VLAN to “No-override” Status

Assigning a DSCP Policy Based on the Source-Port

This option assigns a previously configured DSCP policy (codepoint and 802.1p priority) to outbound IP packets (received from the specified source-ports). That is, the switch:

1. Selects an incoming IP packet on the basis of its source-port on the switch.
2. Overwrites the packet’s DSCP with the DSCP configured in the switch for such packets.
3. Assigns the 802.1p priority configured in the switch for the new DSCP. (Refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 5-55.)
4. Forwards the packet through the appropriate outbound port queue.

For more on DSCP, refer to “Terminology” on page 5-6.

Steps for Creating a Policy Based on Source-Port Classifiers.

Note

You can select one DSCP per source-port. Also, configuring a new DSCP for a source-port automatically overwrites (replaces) any previous DSCP or 802.1p priority configuration for that port.)

1. Identify the source-port classifier to which you want to assign a DSCP policy.
2. Determine the DSCP policy for packets having the selected source-port:
 - a. Determine the DSCP you want to assign to the selected packets. (This codepoint will be used to overwrite the DSCP carried in packets received through the source-port from upstream devices.)
 - b. Determine the 802.1p priority you want to assign to the DSCP.

3. Configure the DSCP policy by using **qos dscp-map** to configure the priority for each codepoint. (For details, refer to the example later in this section and to “Differentiated Services Codepoint (DSCP) Mapping” on page 5-55.)

Note

A codepoint must have an 802.1p priority assignment (0 - 7) before you can configure that codepoint as a criteria for prioritizing packets by source-port. If a codepoint shows **No-override** in the **Priority** column of the DSCP Policy Table (**show qos dscp-map**), then you must assign a 0 - 7 priority before proceeding.

4. Configure the switch to assign the DSCP policy to packets from the specified source-port.

Syntax: `qos dscp-map < codepoint > priority < 0 - 7 >`

*This command is optional if a priority has already been assigned to the < codepoint >. The command creates a DSCP policy by assigning an 802.1p priority to a specific DSCP. When the switch applies this priority to a packet, the priority determines the packet's queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. (Default: For most codepoints, **No-override**. See figure 5-9 on page 5-56 on page 5-56.)*

Syntax: `interface < port-list > qos dscp < codepoint >`

*Assigns a DSCP policy to packets from the specified source-port(s), and overwrites the DSCP in these packets with the assigned < codepoint > value. This policy includes an 802.1p priority and determines the packet's queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. (Default: **No-override**)*

Syntax: `no interface [e] < port-list > qos`

Removes QoS classifier for the specified source-port(s).

Syntax: `show qos source-port`

Displays a listing of all source-port QoS classifiers currently in the running-config file.

For example, suppose you wanted to assign this set of priorities:

Source-Port	DSCP	Priority
A2	000111	7
B1-B3	000101	5
B4, C2	000010	1

1. Determine whether the DSCPs already have priority assignments, which could indicate use by existing applications. This is not a problem as long as the configured priorities are acceptable for all applications using the same DSCP. (Refer to the “Notes on Changing a Priority Setting” on page 5-58. Also, a DSCP must have a priority configured before you can assign any QoS classifiers to use it.)

```
ProCurve(config)# show qos dscp-map
DSCP -> 802.p priority mappings
DSCP policy 802.1p tag Policy name
-----
000000 No-override
000001 No-override
000010 No-override
000011 No-override
000100 No-override
000101 No-override
000110 No-override
000111 No-override
:
:
```

The DSCPs for this example have not yet been assigned an 802.1p priority level.

Figure 5-29. Display the Current Configuration in the DSCP Policy Table

2. Configure the priorities for the DSCPs you want to use.

```
ProCurve(config)# qos dscp-map 000111 priority 7
ProCurve(config)# qos dscp-map 000101 priority 5
ProCurve(config)# qos dscp-map 000010 priority 1
ProCurve(config)# show qos dscp-map
DSCP -> 802.p priority mappings
DSCP policy 802.1p tag Policy name
-----
000000 No-override
000001 No-override
000010 1
000011 No-override
000100 No-override
000101 5
000110 No-override
000111 7
001000 No-override
:
:
```

Priorities Configured in this step.

Figure 5-30. Assign Priorities to the Selected DSCPs

3. Assign the DSCP policies to the selected source-ports and display the result.

```

ProCurve(eth-A2)# int e b4,c2
ProCurve(eth-B4,C2)# qos dscp 000010
ProCurve(eth-B4,C2)# int e b1-b3
ProCurve(eth-B1-B3)# qos dscp 000101
ProCurve(eth-B1-B3)# int e a2
ProCurve(eth-A2)# qos dscp 000111
ProCurve(eth-A2)# show qos port-priority
  
```

Port	Apply rule	DSCP	Priority	Radius Override
A1	No-override		No-override	No-override
A2	DSCP	000111	7	No-override
A3	No-override		No-override	No-override
A4	No-override		No-override	No-override
B1	DSCP	000101	5	No-override
B2	DSCP	000101	5	No-override
B3	DSCP	000101	5	No-override
B4	DSCP	000010	1	No-override
C1	No-override		No-override	No-override
C2	DSCP	000010	1	No-override
C3	No-override		No-override	No-override
C4	No-override		No-override	No-override

Figure 5-31. The Completed Source-Port DSCP-Priority Configuration

Radius Override Field. During a client session authenticated by a RADIUS server, the server can impose a port priority that applies only to that client session. Refer to the RADIUS chapter in the *Access Security Guide* for your switch.

Differentiated Services Codepoint (DSCP) Mapping

The DSCP Policy Table associates an 802.1p priority with a specific ToS byte codepoint in an IPv4 packet. This enables you to set a LAN policy that operates independently of 802.1Q VLAN-tagging.

In the default state, most of the 64 codepoints do not assign an 802.1p priority, as indicated by **No-override** in table 5-9 on page 5-56.

You can use the following command to list the current DSCP Policy table, change the codepoint priority assignments, and assign optional names to the codepoints.

Syntax: show qos dscp-map

Displays the DSCP Policy Table.

qos dscp-map < **codepoint** > priority < 0 - 7 > [name < **ascii-string** >]

Configures an 802.1p priority for the specified codepoint and, optionally, an identifying (policy) name.

no qos dscp-map < **codepoint** >

*Reconfigures the 802.1p priority for <codepoint> to **No-override**. Also deletes the codepoint policy name, if configured.*

no qos dscp-map < codepoint > name

*Deletes only the **policy name**, if configured, for <codepoint>.*

Table 5-9. The Default DSCP Policy Table

DSCP Policy	802.1p Priority	DSCP Policy	802.1p Priority	DSCP Policy	802.1p Priority
000000	No-override	010110	3*	101011	No-override
000001	No-override	010111	No-override	101100	No-override
000010	No-override	011000	No-override	101101	No-override
000011	No-override	011001	No-override	101110	7**
000100	No-override	011010	4*	101111	No-override
000101	No-override	011011	No-override	110000	No-override
000110	No-override	011100	4*	110001	No-override
000111	No-override	011101	No-override	110010	No-override
001000	No-override	011110	5*	110011	No-override
001001	No-override	011111	No-override	110100	No-override
001010	1*	100000	No-override	110101	No-override
001011	No-override	100001	No-override	110110	No-override
001100	1*	100010	6*	110111	No-override
001101	No-override	100011	No-override	111000	No-override
001110	2*	100100	6*	111001	No-override
001111	No-override	100101	No-override	111010	No-override
010000	No-override	100110	7*	111011	No-override
010001	No-override	100111	No-override	111100	No-override
010010	0 *	101000	No-override	111101	No-override
010011	No-override	101001	No-override	111110	No-override
010100	0 *	101010	No-override	111111	No-override
010101	No-override				

*Assured Forwarding codepoints; configured by default on the switches covered in this guide. These codepoints are configured as "No-override" in the Series 3400cl, Series 6400cl and Series 2600/2800 switches.

**Expedited Forwarding codepoint configured by default.

Default Priority Settings for Selected Codepoints

In a few cases, such as 001010 and 001100, a default policy (implied by the DSCP standards for Assured-Forwarding and Expedited-Forwarding) is used. You can change the priorities for the default policies by using **qos dscp-map <codepoint> priority <0 - 7>**. (These policies are not in effect unless you have either applied the policies to a QoS classifier or configured QoS Type-of-Service to be in **diff-services** mode.)

Quickly Listing Non-Default Codepoint Settings

Table 5-9 lists the switch's default codepoint/priority settings. If you change the priority of any codepoint setting to a non-default value and then execute **write memory**, the switch will list the non-default setting in the show config display.

For example, in the default configuration, the following codepoint settings are true:

Codepoint	Default Priority
001100	1
001101	No-override
001110	2

If you change all three settings to a priority of 3, and then execute **write memory**, the switch will reflect these changes in the show config listing:

```
ProCurve(config)# qos dscp-map 001100 priority 3
ProCurve(config)# qos dscp-map 001101 priority 3
ProCurve(config)# qos dscp-map 001110 priority 3
ProCurve(config)# write memory
ProCurve(config)# show config
Startup configuration:

; J8697A Configuration Editor: Created on release #K.11.00

hostname "ProCurve"
time daylight-time-rule None
cdp run
qos dscp-map 001100 priority 3
qos dscp-map 001101 priority 3
qos dscp-map 001110 priority 3
module 2 type J4821A
module 3 type J4820A
. . .
. . .
. . .
```

Configure these three codepoints with non-default priorities.

Show config lists the non default codepoint settings.

Figure 5-32. Example of Show Config Listing with Non-Default Priority Settings in the DSCP Table

Effect of “No-override”. In the QoS Type-of-Service differentiated services mode, a **No-override** assignment for the codepoint of an outbound packet means that QoS is effectively disabled for such packets. That is, QoS does not

affect the packet queuing priority or VLAN tagging. In this case, the packets are handled as follows (as long as no other QoS feature creates priority assignments for them):

802.1Q Status	Outbound 802.1p Priority
Received and Forwarded on a tagged port member of a VLAN.	Unchanged
Received on an Untagged port member of a VLAN; Forwarded on a tagged port member of a VLAN.	0 (zero)—“normal”
Forwarded on an Untagged port member of a VLAN.	None

Notes on Changing a Priority Setting

If a QoS classifier is using a policy (codepoint and associated priority) in the DSCP Policy table, you must delete or change this usage before you can change the priority setting on the codepoint. Otherwise the switch blocks the change and displays this message:

```
Cannot modify DSCP Policy < codepoint > - in use by  
other qos rules.
```

In this case, use **show qos < classifier >** to identify the specific classifiers using the policy you want to change; that is:

```
show qos device-priority  
show qos port-priority  
show qos tcp-udp-port-priority  
show qos vlan-priority  
show qos type-of-service
```

For example, suppose that the 000001 codepoint has a priority of 6, and several classifiers use the 000001 codepoint to assign a priority to their respective types of traffic. If you wanted to change the priority of codepoint 000001 you would do the following:

1. Identify which QoS classifiers use the codepoint.
2. Change the classifier configurations by assigning them to a different DSCP policy, or to an 802.1p priority, or to **No-override**.
3. Reconfigure the desired priority for the 000001 codepoint.
4. Either reassign the classifiers to the 00001 codepoint policy or leave them as they were after step 2, above.

Error Messages caused by DSCP Policy Changes

Refer to the following table on ways to fix errors that may be generated when configuring DSCP policy changes.

Message	Meaning
DSCP Policy < <i>decimal-codepoint</i> > not configured	You have attempted to map a QoS classifier to a codepoint for which there is no configured priority (No-override). Use the qos dscp-map command to configure a priority for the codepoint, then map the classifier to the codepoint.
Cannot modify DSCP Policy < <i>codepoint</i> > - in use by other qos rules.	You have attempted to map a QoS classifier to a codepoint that is already in use by other QoS classifiers. Before remapping the codepoint to a new priority, you must reconfigure the other QoS classifiers so that they do not use this codepoint. You can have multiple QoS classifiers use this same codepoint as long as it is acceptable for all such classifiers to use the same priority.

Table 5-10. Error Messages Generated by DSCP Policy Changes

Example of Changing the Priority Setting on a Policy When One or More Classifiers Are Currently Using the Policy

Suppose that codepoint 000001 is in use by one or more classifiers. If you try to change its priority, you see a result similar to the following:

```
ProCurve(config)# qos dscp-map 000001 priority 2
Cannot modify DSCP Policy 000001 - in use by other qos rules.
```

Figure 5-33. Example of Trying To Change the Priority on a Policy In Use by a Classifier

In this case, you would use steps similar to the following to change the priority.

1. Identify which classifiers use the codepoint you want to change.

Quality of Service (QoS): Managing Bandwidth More Effectively

Differentiated Services Codepoint (DSCP) Mapping

Figure 5-34. Example of a Search to Identify Classifiers Using a Codepoint You Want To Change

2. Change the classifier configurations by assigning them to a different DSCP policy, or to an 802.1p priority, or to **No-override**. For example:
 - a. Delete the policy assignment for the **device-priority** classifier. (That is, assign it to **No-override**.)
 - b. Create a new DSCP policy to use for re-assigning the remaining classifiers.
 - c. Assign the **port-priority** classifier to the new DSCP policy.
 - d. Assign the **udp-port 1260** classifier to an 802.1p priority.

```
(a) ProCurve(config)# no qos device-priority 10.26.50.104
(b) ProCurve(config)# qos dscp-map 000100 priority 6
(c) ProCurve(config)# int e a3 qos dscp 000100
(d) ProCurve(config)# qos udp-port 1260 priority 2
```

3. Reconfigure the desired priority for the 000001 codepoint.
ProCurve(config)# qos dscp-map 000001 priority 4
4. You could now re-assign the classifiers to the original policy codepoint or leave them as currently configured.

QoS Queue Configuration

QoS queue configuration allows you to reduce the number of outbound queues that all switch ports will use to buffer packets for 802.1p user priorities. By default, there are four priority queues or traffic classes. Using this feature, you can reconfigure the switch to eight-queue mode or two-queue mode to increase the available bandwidth per queue.

Use the following commands to change the number of queues per port and display the current priority queue configuration on the switch.

Syntax: qos queue-config < 2-queues | 4-queues | 8-queues >

Configures the number of outbound priority queues for all ports on the switch using one of the following options:

2-queues, 4-queues, or 8-queues.

(Default: 4 queues)

Caution: *This command will execute a “write memory” followed by an immediate reboot, replacing the Startup configuration with the content of the current Running configuration.*

The new configuration will:

- 1. Remove any previously configured “bandwidth-min output” settings*
- 2. Set the new number of outbound port queues*

If you select anything but “yes” for this operation, the operation is aborted and a message stating “Operation aborted” appears.

show qos queue config

Displays the current qos queue configuration.

Mapping of Outbound Port Queues. The mapping of 802.1p priorities to outbound port queues is shown in Table 5-11.

Table 5-11. Mapping of 802.1p Priorities to Outbound Port Queues

802.1p Priority	8 Queues	4 Queues (default)	2 Queues
1 (lowest)	1	1	1
2	2		
0 (normal)	3	2	
3	4		
4	5	3	2
5	6		
6	7	4	
7 (highest)	8		

Impact of QoS Queue Configuration on Guaranteed Minimum Bandwidth (GMB). Changing the number of queues removes any **bandwidth-min output** settings in the startup configuration, and automatically re-allocates the GMB per queue as shown in Table 5-12.

Table 5-12. Default GMB Percentage Allocations per QoS Queue Configuration

802.1p Priority	8 Queues	4 Queues (default)	2 Queues
1 (lowest)	2%	10%	90%
2	3%		
0 (normal)	30%	70%	
3	10%		
4	10%	10%	10%
5	10%		
6	15%	10%	
7 (highest)	20%		

Note

For more information on configuring GMB, refer to the chapter titled “*Port Traffic Controls*” in the *Management and Configuration Guide*.

Configuring the Number of Priority Queues

To change the number of outbound priority queues for all ports on the switch, use the **qos queue-config** command.

Caution

This command will execute a **write memory** followed by an immediate reboot, replacing the Startup configuration with the contents of the current Running configuration. In addition to setting the number of outbound port queues, the new configuration will remove any previously configured **bandwidth-min output** settings.

For example, to change the number of outbound priority queues for all ports on the switch from eight queues to four:

1. Specify the number of outbound priority queues to be configured using the **qos queue-config** command.

```
ProCurve(config)# qos queue-config 4-queues
```

A caution message appears (see Caution above for details) concluding with the following prompt.

```
Do you wish to proceed? [Proceed/Cancel]
```

2. Type **Proceed** to continue.

A second confirmation prompt appears:

```
Please confirm reset. [Yes/Cancel]
```

3. Type **Yes** to initiate a write memory followed by an immediate reboot (entering **Cancel** at either of the two prompts will cancel the command and maintain the current queue configuration on the switch).

The changes will be committed to the startup configuration and the switch will reboot automatically with the new priority queue changes in effect (see Table 5-12 on page 5-63 for a listing of the default GMB percentages that are allocated per queue).

Viewing the QoS Queue Configuration

To display the current priority queue configuration and memory allocations per queue, use the **show qos queue-config** command.

```
ProCurve#: show qos queue-config
```

Queue	802.1p Priority	Memory %
-----	-----	-----
1	1-2	10
2	0,3	70
3	4-5	10
4	6-7	10

Figure 5-35. Displaying QoS Queue Configuration

QoS Operating Notes and Restrictions

QoS support based on packet type is shown below.

Table 5-13. Details of Packet Criteria and Restrictions for QoS Support

Packet Criteria or Restriction	QoS Classifiers							DSCP Overwrite (Re-Marking)
	UDP/TCP	Device Priority (IP Address)	IP Type-of-Service	Layer 3 Protocol	VLAN	Source Port	Incoming 802.1p	
Restricted to IPv4 Packets Only	Yes	Yes	Yes	No	No	No	No	Yes
Allow Packets with IP Options ¹	Yes	Yes ²	Yes ²	Yes ²	Yes ²	Yes ²	Yes ²	No
Support IPv6 Packets ¹	No	No	No	Yes	Yes	Yes	Yes	No
Support Layer-2 SAP Encapsulation	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes

¹For explicit QoS support of IPv6 packets, force IPv6 traffic into its own set of VLANs and then configure VLAN-based classifiers for those VLANs.

²On IPv4 packets with IP options, the switches covered in this guide support QoS for 802.1p priority policies, but does **not** do any DSCP re-marking for DSCP policies.

- **All Switches:** For explicit QoS support of IP subnets, ProCurve recommends forcing IP subnets onto separate VLANs and then configuring VLAN-based classifiers for those VLANs.
- **For Devices that Do Not Support 802.1Q VLAN-Tagged Ports:** For communication between these devices and the switch, connect the device to a switch port configured as **Untagged** for the VLAN in which you want the device's traffic to move.
- **Port Tagging Rules:** For a port on the switch to be a member of a VLAN, the port must be configured as either **Tagged** or **Untagged** for that VLAN. A port can be an untagged member of only one VLAN of a given protocol type. Otherwise, the switch cannot determine which VLAN should receive untagged traffic. For more on VLANs, refer to chapter 2, "Static Virtual LANs (VLANs)".
- **Maximum QoS Configuration Entries:** The switches covered in this guide accept the maximum outbound priority and/or DSCP policy configuration entries shown in table 5-14.

Table 5-14. Maximum QoS Entries.

Switch	Software Version	Maximum QoS Entries	Notes
Switch 2900	T.13.01	250*	- Each device (IP address) QoS configuration uses two entries. - Each TCP/UDP port QoS configuration uses two entries. - All other classifier configurations use one entry each.
*Configuring device (IP address) or TCP/UDP QoS entries reduces this maximum. See the "Notes" column.			

Attempting to exceed the above limits generates the following message in the CLI:

Unable to add this QoS rule. Maximum number (entry-#) already reached.

- **Non-Supported IP Packets:** The DSCP policy codepoint-remarking operation is not supported in any QoS classifier for packets carrying IP options in the packet header.
- **Not Supported:** Use of an inbound 802.1p packet priority as a classifier for remapping a packet's outbound priority to different 802.1p priority. For example, where inbound packets carry an 802.1p priority of 1, QoS cannot be configured use this priority as a classifier for changing the outbound priority to 0.
- **Monitoring Shared Resources:** The QoS feature shares internal switch resources with several other features. The switch provides ample resources for all features. However, if the internal resources become fully subscribed, additional QoS provisions cannot be configured until the necessary resources are released from other uses. For information on determining the current resource availability and usage, refer to the appendix titled "Monitoring Resources" in the *Management and Configuration Guide* for your switch.

IP Multicast (IGMP) Interaction with QoS

IGMP high-priority-forward causes the switch to service the subscribed IP multicast group traffic at high priority, even if QoS on the switch has relegated the traffic to a lower priority. This does not affect any QoS priority settings, so the QoS priority is honored by downstream devices. However, QoS does take precedence over IGMP normal-priority traffic.

The switch's ability to prioritize IGMP traffic for either a normal or high priority outbound queue overrides any QoS criteria, and does not affect any 802.1p priority settings the switch may assign. For a given packet, if both IGMP high priority and QoS are configured, the QoS classification occurs and the switch marks the packet for downstream devices, but the packet is serviced by the high-priority queue when leaving the switch.

IGMP High Priority	QoS Configuration Affects Packet	Switch Port Output Queue	Outbound 802.1p Setting (Requires Tagged VLAN)
Not Enabled	Yes	Determined by QoS	Determined by QoS
Enabled	See above paragraph.	High	As determined by QoS if QoS is active.

Introduction to Stack Management

ProCurve Stack Management (*stacking*) enables you to use a single IP address and standard network cabling to manage a group of up to 16 total switches in the same IP subnet (broadcast domain). Using stacking, you can:

- Reduce the number of IP addresses needed in your network.
- Simplify management of small workgroups or wiring closets while scaling your network to handle increased bandwidth demand.
- Eliminate any specialized cables for stacking connectivity and remove the distance barriers that typically limit your topology options when using other stacking technologies.
- Add switches to your network without having to first perform IP addressing tasks.

Stacking Support on ProCurve Switches

As of January 2008, the following ProCurve switches include stacking:

- | | |
|--------------------------|---|
| ■ ProCurve Series 6400cl | ■ ProCurve Series 2500 |
| ■ ProCurve Series 6200yl | ■ ProCurve Switch 8000M ^{1, 2} |
| ■ ProCurve Switch 6108 | ■ ProCurve Switch 4000M ^{1, 2} |
| ■ ProCurve Series 4200vl | ■ ProCurve Switch 2424M ^{1, 2} |
| ■ ProCurve Series 4100gl | ■ ProCurve Switch 2400M ^{1, 2} |
| ■ ProCurve Series 3500yl | ■ ProCurve Switch 1600M ^{1, 2} |
| ■ ProCurve Series 3400cl | |
| ■ ProCurve Switch 2900 | |
| ■ ProCurve Series 2600 | |
| ■ ProCurve Series 2800 | |

¹Requires software release C.08.03 or later, which is included with the 8000M, 4000M, 2424M, and 1600M models as of July, 2000. Release C.08.03 or a later version is also available on the ProCurve Networking web site at www.procurve.com. (Click on **Software updates**.)

²Discontinued product.

Note

Stacking and meshing cannot both be enabled at the same time on a Series 3500yl switch or a 6200yl switch.

In the default configuration, stacking in the “candidate” state is enabled on the Series 3500yl switches and on the 6200yl switch.

Summary of Stacking Features

Feature	Default	Menu	CLI	Web
view stack status				
view status of a single switch	n/a	page 6-26 thru page 6-28	page 6-31	Refer to Online Help
view candidate status	n/a	↑	page 6-31	
view status of commander and its stack	n/a		page 6-32	
view status of all stacking-enabled switches in the ip subnet	n/a		page 6-32	
configure stacking				
enable/disable candidate Auto-Join	enabled/Yes	page 6-15	page 6-37	↑
“push” a candidate into a stack	n/a	page 6-15	page 6-37	
configure a switch to be a commander	n/a	page 6-13	page 6-33	
“push” a member into another stack	n/a	page 6-24	page 6-39	
remove a member from a stack	n/a	page 6-21	page 6-40 or page 6-41	
“pull” a candidate into a stack	n/a	page 6-17	page 6-36	
“pull” a member from another stack	n/a	page 6-19	page 6-38	
convert a commander or member to a member of another stack	n/a	page 6-24	page 6-39	
access member switches for configuration and traffic monitoring	n/a	page 6-23	page 6-42	
disable stacking	enabled	page 6-15	page 6-44	
transmission interval	60 seconds	page 6-13	page 6-44	

Components of ProCurve Stack Management

Table 6-1. Stacking Definitions

Stack	Consists of a Commander switch and any Member switches belonging to that Commander's stack.
Commander	A switch that has been manually configured as the controlling device for a stack. When this occurs, the switch's stacking configuration appears as Commander .
Candidate	A switch that is ready to join (become a Member of) a stack through either automatic or manual methods. A switch configured as a Candidate is not in a stack.
Member	A switch that has joined a stack and is accessible from the stack Commander.

Figure 6-1. Illustration of a Switch Moving from Candidate to Member

General Stacking Operation

After you configure one switch to operate as the Commander of a stack, additional switches can join the stack by either automatic or manual methods. After a switch becomes a Member, you can work through the Commander switch to further configure the Member switch as necessary for all of the additional software features available in the switch.

The Commander switch serves as the in-band entry point for access to the Member switches. For example, the Commander's IP address becomes the path to all stack Members and the Commander's Manager password controls access to all stack Members.

Figure 6-2. Example of Stacking with One Commander Controlling Access to Wiring Closet Switches

Interface Options. You can configure stacking through the switch's menu interface, CLI, or the web browser interface. For information on how to use the web browser interface to configure stacking, see the online Help for the web browser interface.

Web Browser Interface Window for Commander Switches. The web browser interface window for a Commander switch differs in appearance from the same window for non-commander switches.

Operating Rules for Stacking

General Rules

- Stacking is an optional feature (enabled in the default configuration) and can easily be disabled. Stacking has no effect on the normal operation of the switch in your network.
- A stack requires one Commander switch. (Only one Commander allowed per stack.)
- All switches in a particular stack must be in the same IP subnet (broadcast domain). A stack cannot cross a router.
- A stack accepts up to 16 switches (numbered 0-15), including the Commander (always numbered 0).
- The stacking feature supports up to 100 switches in the same IP subnet (broadcast domain), however, a switch can belong to only one stack. In the event that the 100 switch limit is exceeded, it may take multiple attempts to add or move a member to any given stack. Once a member is added to a stack, it is not “forgotten” by the Commander.
- The **stack status (all)** command will display up to 100 devices. Devices that are not members of a given stack may periodically “drop out” of the list.
- If multiple VLANs are configured, stacking uses only the primary VLAN on any switch. In the factory-default configuration, the DEFAULT_VLAN is the primary VLAN. (See “Stacking Operation with Multiple VLANs Configured” on page 6-44 and “The Primary VLAN” on page 2-46.)
- Stacking allows intermediate devices that do not support stacking. This enables you to include switches that are distant from the Commander.

Figure 6-3. Example of a Non-Stacking Device Used in a Stacking Environment

Specific Rules

Table 6-2. Specific Rules for Commander, Candidate, and Member Switch

	IP Addressing and Stack Name	Number Allowed Per Stack	Passwords	SNMP Communities
Commander	IP Addr: Requires an assigned IP address and mask for access via the network. Stack Name: Required	Only one Commander switch is allowed per stack.	The Commander's Manager and Operator passwords are assigned to any switch becoming a Member of the stack. If you change the Commander's passwords, the Commander propagates the new passwords to all stack Members.	Standard SNMP community operation. The Commander also operates as an SNMP proxy to Members for all SNMP communities configured in the Commander.
Candidate	IP Addr: Optional. Configuring an IP address allows access via Telnet or web browser interface while the switch is not a stack member. In the factory default configuration the switch automatically acquires an IP address if your network includes DHCP service. Stack Name: N/A	n/a	Passwords optional. If the Candidate becomes a stack Member, it assumes the Commander's Manager and Operator passwords. If a candidate has a password, it cannot be automatically added to a stack. In this case, if you want the Candidate in a stack, you must manually add it to the stack.	Uses standard SNMP community operation if the Candidate has its own IP addressing.
Member	IP Addr: Optional. Configuring an IP address allows access via Telnet or web browser interface without going through the Commander switch. This is useful, for example, if the stack Commander fails and you need to convert a Member switch to operate as a replacement Commander. Stack Name: N/A	Up to 15 Members per stack.	When the switch joins the stack, it automatically assumes the Commander's Manager and Operator passwords and discards any passwords it may have had while a Candidate. Note: If a Member leaves a stack for any reason, it retains the passwords assigned to the stack Commander at the time of departure from the stack.	Belongs to the same SNMP communities as the Commander (which serves as an SNMP proxy to the Member for communities to which the Commander belongs). To join other communities that <i>exclude</i> the Commander, the Member must have its own IP address. Loss of stack membership means loss of membership in any community that is configured only in the Commander. See "SNMP Community Operation in a Stack" on page 6-43.

Note

In the default stack configuration, the Candidate **Auto Join** parameter is enabled, but the Commander **Auto Grab** parameter is disabled. This prevents Candidates from automatically joining a stack prematurely or joining the wrong stack (if more than one stack Commander is configured in a subnet or broadcast domain). If you plan to install more than one stack in a subnet, HP recommends that you leave **Auto Grab** disabled on all Commander switches and manually add Members to their stacks. Similarly, if you plan to install a stack in a subnet (broadcast domain) where stacking-capable switches are not intended for stack membership, you should set the **Stack State** parameter (in the Stack Configuration screen) to **Disabled** on those particular switches.

Configuring Stack Management

Overview of Configuring and Bringing Up a Stack

This process assumes that:

- All switches you want to include in a stack are connected to the same subnet (broadcast domain).
- If VLANs are enabled on the switches you want to include in the stack, then the ports linking the stacked switches must be on the primary VLAN in each switch (which, in the default configuration, is the default VLAN). If the primary VLAN is tagged, then each switch in the stack must use the same VLAN ID (VID) for the primary VLAN. (Refer to “The Primary VLAN” on page 2-46, and “Stacking Operation with Multiple VLANs Configured” on page 6-44.)
- *If you are including a ProCurve Switch 8000M, 4000M, 2424M, 2400M, or 1600M in a stack, you must first update all such devices to software version C.08.03 or later. (You can get a copy of the latest software version from the ProCurve Networking web site and/or copy it from one switch to another. For downloading instructions, see appendix A, “File Transfers”, in the *Management and Configuration Guide* for your switch.)*

Options for Configuring a Commander and Candidates. Depending on how Commander and Candidate switches are configured, Candidates can join a stack either automatically or by a Commander manually adding (“pulling”) them into the stack. In the default configuration, a Candidate joins only when *manually* pulled by a Commander. You can reconfigure a Commander to *automatically* pull in Candidates that are in the default stacking configuration. You can also reconfigure a Candidate switch to either “push” itself into a particular Commander’s stack, convert the Candidate to a Commander (for a stack that does not already have a Commander), or to operate as a standalone switch without stacking. The following table shows your control options for adding Members to a stack.

Table 6-3. Stacking Configuration Guide

Join Method ¹	Commander (IP Addressing Required)	Candidate (IP Addressing Optional)	
	Auto Grab	Auto Join	Passwords
Automatically add Candidate to Stack (Causes the first 15 eligible, discovered switches in the subnet to automatically join a stack.)	Yes	Yes (<i>default</i>)	No (<i>default</i>)*
Manually add Candidate to Stack (Prevent automatic joining of switches you don’t want in the stack)	No (<i>default</i>)	Yes (<i>default</i>)	Optional*
	Yes	No	Optional*
	Yes	Yes (<i>default</i>) or No	Configured
Prevent a switch from being a Candidate	N/A	Disabled	Optional

*The Commander’s Manager and Operator passwords propagate to the candidate when it joins the stack.

The easiest way to *automatically* create a stack is to:

1. Configure a switch as a Commander.
2. Configure IP addressing and a stack name on the Commander.
3. Set the Commander’s **Auto Grab** parameter to **Yes**.
4. Connect Candidate switches (in their factory default configuration) to the network.

This approach automatically creates a stack of up to 16 switches (including the Commander). However this replaces manual control with an automatic process that may bring switches into the stack that you did not intend to include. With the Commander’s **Auto Grab** parameter set to **Yes**, *any switch* conforming to all four of the following factors automatically becomes a stack Member:

- Default stacking configuration (**Stack State** set to **Candidate**, and **Auto Join** set to **Yes**)
- Same subnet (broadcast domain) and default VLAN as the Commander (If VLANs are used in the stack environment, see “Stacking Operation with a Tagged VLAN” on page 6-44.)
- No Manager password
- 14 or fewer stack members at the moment

General Steps for Creating a Stack

This section describes the general stack creation process. For the detailed configuration processes, see pages 6-13 through 6-36 for the menu interface and pages 6-29 through 6-41 for the CLI.

1. Determine the naming conventions for the stack. You will need a stack name. Also, to help distinguish one switch from another in the stack, you can configure a unique system name for each switch. Otherwise, the system name for a switch appearing in the Stacking Status screen appears as the stack name plus an automatically assigned switch number. For example:

```

Pacific Ocean
-----
----- CONSOLE - MANAGER MODE -----
Stacking - Stacking Status (All)

Stack Name      MAC Address      System Name      Status
-----
Big Waters      (0060b0-880a80   Pacific Ocean )  Commander Up
                (0060b0-df1a00   Coral Sea       )  Member Up
Online          (0060b0-df7680   online-0       )  Commander Up
                (001083-3c7480   online-1       )  Member Up
                (0060b0-312f00   online-2       )  Member Up
                (001083-3c09c0   online-3       )  Member Up

Actions->  Back  Next page  Prev page  Help
Return to previous screen.
Use up/down arrow keys to scroll to other entries, left/right arrow keys to
change action selection, and <Enter> to execute action.

```

For status descriptions, see the table on page 6-45.

Stack with unique system name for each switch.

Stack named "Online" with no previously configured system names assigned to individual switches.

Figure 6-4. Using the System Name to Help Identify Individual Switches

2. Configure the Commander switch. Doing this first helps to establish consistency in your stack configuration, which can help prevent startup problems.
 - A stack requires one Commander switch. If you plan to implement more than one stack in a subnet (broadcast domain), the easiest way to avoid unintentionally adding a Candidate to the wrong stack is to manually control the joining process by leaving the Commander's **Auto Grab** parameter set to **No** (the default).
 - The Commander assigns its Manager and Operator passwords to any Candidate switch that joins the stack.
 - The Commander's SNMP community names apply to members.
3. For automatically or manually pulling Candidate switches into a stack, you can leave such switches in their default stacking configuration. If you need to access Candidate switches through your network before they join the stack, assign IP addresses to these devices. Otherwise, IP addressing is optional for Candidates and Members. (Note that once a Candidate becomes a member, you can access it through the Commander to assign IP addressing or make other configuration changes.)
4. Make a record of any Manager passwords assigned to the switches (intended for your stack) that are not currently members. (You will use these passwords to enable the protected switches to join the stack.)
5. If you are using VLANs in the stacking environment, you must use the default VLAN for stacking links. For more information, see "Stacking Operation with a Tagged VLAN" on page 6-44.
6. Ensure that all switches intended for the stack are connected to the same subnet (broadcast domain). As soon as you connect the Commander, it will begin discovering the available Candidates in the subnet.
 - If you configured the Commander to automatically add Members (**Auto Grab = Yes**), the first fifteen discovered Candidates meeting both of the following criteria will automatically join the stack:
 - **Auto Join** parameter set to **Yes** (the default)
 - Manager password not configured
 - If you configured the Commander to manually add Members (**Auto Grab** set to **No**—the default), you can begin the process of selecting and adding the desired Candidates.
7. Ensure that all switches intended for the stack have joined.
8. If you need to do specific configuration or monitoring tasks on a Member, use the console interface on the Commander to access the Member.

Using the Menu Interface To View Stack Status and Configure Stacking

Using the Menu Interface To View and Configure a Commander Switch

1. Configure an IP address and subnet mask on the Commander switch.
(Refer to the *Management and Configuration Guide* for your switch.)
2. Display the Stacking Menu by selecting **Stacking** in the Main Menu.

```

                                DEFAULT_CONFIG
=====-- CONSOLE - MANAGER MODE --=====
                                Stacking Menu

1. Stacking Status (This Switch)
2. Stacking Status (All)
3. Stack Configuration
0. Return to Main Menu...

Shows the status of Stack.
To select menu item, press item number, or highlight item and press <Enter>.
```

Figure 6-5. The Default Stacking Menu

3. Display the Stack Configuration menu by pressing [3] to select **Stack Configuration**.

```

                                DEFAULT_CONFIG
=====-- CONSOLE - MANAGER MODE --=====
                                Stacking - Stack Configuration

Stack State : Candidate
Auto Join [Yes] : Yes
Transmission Interval [60] : 60

Actions->  Cancel  Edit  Save  Help

Cancel changes and return to previous screen.
Use arrow keys to change action selection and <Enter> to execute action.
```

Figure 6-6. The Default Stack Configuration Screen

4. Move the cursor to the Stack State field by pressing [E] (for **Edit**). Then use the Space bar to select the **Commander** option.
5. Press the downarrow key to display the Commander configuration fields in the Stack Configuration screen.

Figure 6-7. The Default Commander Configuration in the Stack Configuration Screen

6. Enter a unique stack name (up to 15 characters; no spaces) and press the downarrow key.
7. Ensure that the Commander has the desired **Auto Grab** setting, then press the downarrow key:
 - **No** (the default) prevents automatic joining of Candidates that have their **Auto Join** set to **Yes**.
 - **Yes** enables the Commander to automatically take a Candidate into the stack as a Member if the Candidate has **Auto Join** set to **Yes** (the default Candidate setting) and does not have a previously configured password.
8. Accept or change the transmission interval (default: 60 seconds), then press [Enter] to return the cursor to the **Actions** line.
9. Press [S] (for **Save**) to save your configuration changes and return to the Stacking menu.

Your Commander switch should now be ready to automatically or manually acquire Member switches from the list of discovered Candidates, depending on your configuration choices.

Using the Menu To Manage a Candidate Switch

Using the menu interface, you can perform these actions on a Candidate switch:

- Add (“push”) the Candidate into an existing stack
- Modify the Candidate’s stacking configuration (**Auto Join** and **Transmission Interval**)
- Convert the Candidate to a Commander
- Disable stacking on the Candidate so that it operates as a standalone switch

In its default stacking configuration, a Candidate switch can either automatically join a stack or be manually added (“pulled”) into a stack by a Commander, depending on the Commander’s **Auto Grab** setting. The following table lists the Candidate’s configuration options:

Table 6-4. Candidate Configuration Options in the Menu Interface

Parameter	Default Setting	Other Settings
Stack State	Candidate	Commander, Member, or Disabled
Auto Join	Yes	No
Transmission Interval	60 Seconds	Range: 1 to 300 seconds

Using the Menu To “Push” a Switch Into a Stack, Modify the Switch’s Configuration, or Disable Stacking on the Switch. Use Telnet or the web browser interface to access the Candidate if it has an IP address. Otherwise, use a direct connection from a terminal device to the switch’s console port. (For information on how to use the web browser interface, see the online Help provided for the browser.)

1. Display the Stacking Menu by selecting **Stacking** in the console Main Menu.
2. Display the Stack Configuration menu by pressing **[3]** to select **Stack Configuration**.

Figure 6-8. The Default Stack Configuration Screen

3. Move the cursor to the Stack State field by pressing [E] (for **Edit**).
4. Do one of the following:

- To disable stacking on the Candidate, use the Space bar to select the **Disabled** option, then go to step 5.

Note: Using the menu interface to disable stacking on a Candidate removes the Candidate from all stacking menus.

- To insert the Candidate into a specific Commander's stack:
 - i. Use the space bar to select Member.
 - ii. Press [Tab] once to display the **Commander MAC Address** parameter, then enter the MAC address of the desired Commander.
- To change **Auto Join** or **Transmission Interval**, use [Tab] to select the desired parameter, and:
 - To change **Auto Join**, use the Space bar.
 - To change **Transmission Interval**, type in the new value in the range of 1 to 300 seconds.

Note: All switches in the stack must be set to the same transmission interval to help ensure proper stacking operation. HP recommends that you leave this parameter set to the default 60 seconds.

Then go to step 5.

5. press [Enter] to return the cursor to the **Actions** line.

6. Press **[S]** (for **Save**) to save your configuration changes and return to the Stacking menu.

Using the Commander To Manage The Stack

The Commander normally operates as your stack manager and point of entry into other switches in the stack. This typically includes:

- Adding new stack members
- Moving members between stacks
- Removing members from a stack
- Accessing stack members for individual configuration changes and traffic monitoring

The Commander also imposes its passwords on all stack members and provides SNMP community membership to the stack. (See “SNMP Community Operation in a Stack” on page 6-43.)

Using the Commander’s Menu To Manually Add a Candidate to a Stack. In the default configuration, you must manually add stack Members from the Candidate pool. Reasons for a switch remaining a Candidate instead of becoming a Member include any of the following:

- **Auto Grab** in the Commander is set to **No** (the default).
- **Auto Join** in the Candidate is set to **No**.

Note: When a switch leaves a stack and returns to Candidate status, its **Auto Join** parameter resets to **No** so that it will not immediately rejoin a stack from which it has just departed.

- A Manager password is set in the Candidate.
- The stack is full.

Unless the stack is already full, you can use the Stack Management screen to manually convert a Candidate to a Member. If the Candidate has a Manager password, you will need to use it to make the Candidate a Member of the stack.

1. To add a Member, start at the Main Menu and select:

9. Stacking...

4. Stack Management

You will then see the Stack Management screen:

For status descriptions, see the table on page 6-45.

Pacific Ocean

----- CONSOLE - MANAGER MODE -----
Stacking - Stack Management

SN	MAC Address	System Name	Device Type	Status
1	0060b0-df1a00	Coral Sea	3400c1-48G	Member Up
2	080009-8c5080	North Atlantic	3500yl	Member Up

Actions-> **Back** Add Edit Delete Help

Return to previous screen.
Use up/down arrow keys to change record selection, left/right arrow keys to change action selection, and <Enter> to execute action.

Figure 6-9. Example of the Stack Management Screen

- Press **[A]** (for **Add**) to add a Candidate. You will then see this screen listing the available Candidates:

Pacific Ocean

----- CONSOLE - MANAGER MODE -----
Stacking - Stack Management

Switch Number : **3** ← The Commander automatically selects an available switch number (SN). You have the option of assigning any other available number.

MAC Address :
Candidate Password :

Candidate MAC	System Name	Device Type
0060b0-e94300	DEFAULT_CONFIG	3500yl
080009-918f80	DEFAULT_CONFIG	3500yl

← Candidate List

Actions-> Cancel Edit Save Help

Use arrow keys to change field selection, <Space> to toggle field choices, and <Enter> to go to Actions.

Figure 6-10. Example of Candidate List in Stack Management Screen

- Either accept the displayed switch number or enter another available number. (The range is 0 - 15, with 0 reserved for the Commander.)
- Use the downarrow key to move the cursor to the MAC Address field, then type the MAC address of the desired Candidate from the Candidate list in the lower part of the screen.
- Do one of the following:

- If the desired Candidate has a Manager password, press the downarrow key to move the cursor to the Candidate Password field, then type the password.
 - If the desired Candidate does not have a password, go to step 6.
6. Press **[Enter]** to return to the Actions line, then press **[S]** (for **Save**) to complete the Add process for the selected Candidate. You will then see a screen similar to the one in figure 6-11, below, with the newly added Member listed.

Note: If the message **Unable to add stack member: Invalid Password** appears in the console menu's Help line, then you either omitted the Candidate's Manager password or incorrectly entered the Manager password.

For status descriptions, see the table on page 6-45.

Pacific Ocean				
----- CONSOLE - MANAGER MODE -----				
Stacking - Stack Management				
SN	MAC Address	System Name	Device Type	Status
1	0060b0-df1a00	Coral Sea	3500yl	Member Up
2	080009-8c5080	North Atlantic	3400cl-48G	Member Up
3	0060b0-e94300	Big_Waters-3	3500yl	Member Up

New Member added in step 6.

Figure 6-11. Example of Stack Management Screen After New Member Added

Using the Commander's Menu To Move a Member From One Stack to Another. Where two or more stacks exist in the same subnet (broadcast domain), you can easily move a Member of one stack to another stack if the destination stack is not full. (If you are using VLANs in your stack environment, see "Stacking Operation with a Tagged VLAN" on page 6-44.) This procedure is nearly identical to manually adding a Candidate to a stack (page 6-17). (If the stack from which you want to move the Member has a Manager password, you will need to know the password to make the move.)

1. To move a Member from one stack to another, go to the Main Menu of the Commander in the destination stack and display the Stacking Menu by selecting

9. Stacking...
2. To learn or verify the MAC address of the Member you want to move, display a listing of all Commanders, Members, and Candidates in the subnet by selecting:

2. Stacking Status (All)

You will then see the Stacking Status (All) screen:

Figure 6-12. Example of How the Stacking Status (All) Screen Helps You Find Member MAC Addresses

3. In the Stacking Status (All) screen, find the Member switch that you want to move and note its MAC address, then press **[B]** (for **Back**) to return to the Stacking Menu.

4. Display the Commander's Stack Management screen by selecting

4. Stack Management

(For an example of this screen, see figure 6-9 on page 6-18.)

5. Press **[A]** (for **Add**) to add the Member. You will then see a screen listing any available candidates. (See figure 6-10 on page 6-18.) Note that you will not see the switch you want to add because it is a Member of another stack and not a Candidate.)
6. Either accept the displayed switch number or enter another available number. (The range is 0 - 15, with 0 reserved for the Commander.)
7. Use the downarrow key to move the cursor to the MAC Address field, then type the MAC address of the desired Member you want to move from another stack.

8. Do one of the following:
 - If the stack containing the Member you are moving has a Manager password, press the downarrow key to select the Candidate Password field, then type the password.
 - If the stack containing the Member you want to move does not have a password, go to step 9.
9. Press **[Enter]** to return to the Actions line, then press **[S]** (for **Save**) to complete the Add process for the selected Member. You will then see a screen similar to the one in figure 6-9 on page 6-18, with the newly added Member listed.

Note:

If the message **Unable to add stack member: Invalid Password** appears in the console menu's Help line, then you either omitted the Manager password for the stack containing the Member or incorrectly entered the Manager password.

You can “push” a Member from one stack to another by going to the Member's interface and entering the MAC address of the destination stack Commander in the Member's **Commander MAC Address** field. Using this method moves the Member to another stack without a need for knowing the Manager password in that stack, but also blocks access to the Member from the original Commander.

Using the Commander's Menu To Remove a Stack Member. These rules affect removals from a stack:

- When a Candidate becomes a Member, its **Auto Join** parameter is automatically set to **No**. This prevents the switch from automatically rejoining a stack as soon as you remove it from the stack.
- When you use the Commander to remove a switch from a stack, the switch rejoins the Candidate pool for your IP subnet (broadcast domain), with **Auto Join** set to **No**.
- When you remove a Member from a stack, it frees the previously assigned switch number (**SN**), which then becomes available for assignment to another switch that you may subsequently add to the stack. The default switch number used for an add is the lowest unassigned number in the Member range (1 - 15; 0 is reserved for the Commander).

To remove a Member from a stack, use the Stack Management screen.

1. From the Main Menu, select:

9. Stacking...

4. Stack Management

You will then see the Stack Management screen:

Figure 6-13. Example of Stack Management Screen with Stack Members Listed

2. Use the downarrow key to select the Member you want to remove from the stack.

SN	MAC Address	System Name	Device Type	Status
1	0060b0-df1a00	Coral Sea	3500yl	Member Up
2	080009-8c5080	North Atlantic	3500yl	Member Up
3	0060b0-e94300	Big Waters-3	3400cl-48G	Member Up

Figure 6-14. Example of Selecting a Member for Removal from the Stack

3. Type [D] (for **Delete**) to remove the selected Member from the stack. You will then see the following prompt:

Figure 6-15. The Prompt for Completing the Deletion of a Member from the Stack

4. To continue deleting the selected Member, press the Space bar once to select **Yes** for the prompt, then press **[Enter]** to complete the deletion. The Stack Management screen updates to show the new stack Member list.

Using the Commander To Access Member Switches for Configuration Changes and Monitoring Traffic

After a Candidate becomes a stack Member, you can use that stack's Commander to access the Member's console interface for the same configuration and monitoring that you would do through a Telnet or direct-connect access.

1. From the Main Menu, select:

9. Stacking...

5. Stack Access

You will then see the Stack Access screen:

For status descriptions, see the table on page 6-45.

SN	MAC Address	System Name	Device Type	Status
0	0060b0-880a80	Pacific Ocean	HP 2512	Commander Up
1	0060b0-df1a00	Coral Sea	3500yl	Member Up
2	080009-8c5080	North Atlantic	3500yl	Member Up

Actions-> **Cancel** eXecute Help

Return to previous screen.
Use arrow keys to change field selection

Figure 6-16. Example of the Stack Access Screen

Use the down arrow key to select the stack Member you want to access, then press **[X]** (for **eXecute**) to display the console interface for the selected Member. For example, if you selected switch number 1 (system name: **Coral Sea**) in figure 6-16 and then pressed **[X]**, you would see the Main Menu for the switch named Coral Sea.

Figure 6-17. The eXecute Command Displays the Console Main Menu for the Selected Stack Member

2. You can now make configuration changes and/or view status data for the selected Member in the same way that you would if you were directly connected or telnetted into the switch.
3. When you are finished accessing the selected Member, do the following to return to the Commander's Stack Access screen:
 - a. Return to the Member's Main Menu.
 - b. Press **[0]** (for Logout), then **[Y]** (for Yes).
 - c. Press **[Return]**.

You should now see the Commander's Stack Access screen. (For an example, see figure 6-16 on page 6-23.)

Converting a Commander or Member to a Member of Another Stack

When moving a commander, the following procedure returns the stack members to Candidate status (with Auto-Join set to **"No"**) and converts the stack Commander to a Member of another stack. When moving a member, the procedure simply pulls a Member out of one stack and pushes it into another.

1. From the Main Menu of the switch you want to move, select

9. Stacking

2. To determine the MAC address of the destination Commander, select

2. Stacking Status (All)

3. Press **[B]** (for **B**ack) to return to the Stacking Menu.
4. To display Stack Configuration menu for the switch you are moving, select

3. Stack Configuration

5. Press **[E]** (for **E**dit) to select the Stack State parameter.
6. Use the Space bar to select **Member**, then press **[↓]** to move to the **Commander MAC Address** field.
7. Enter the MAC address of the destination Commander and press **[Enter]**.
8. Press **[S]** (for **S**ave).

Monitoring Stack Status

Using the stacking options in the menu interface for any switch in a stack, you can view stacking data for that switch or for all stacks in the subnet (broadcast domain). (If you are using VLANs in your stack environment, see “Stacking Operation with a Tagged VLAN” on page 6-44.) This can help you in such ways as determining the stacking configuration for individual switches, identifying stack Members and Candidates, and determining the status of individual switches in a stack. See table 6-5 on page 6-25.

Table 6-5. Stack Status Environments

Screen Name	Commander	Member	Candidate
Stack Status (This Switch)	• Commander's stacking configuration • Data on stack Members: – Switch Number – MAC Address – System Name – Device Type – Status	• Member's stacking configuration • Member Status • Data identifying Member's Commander: – Commander Status – Commander IP Address – Commander MAC Address	Candidate's stacking configuration
Stack Status (All)	Lists devices by stack name or Candidate status (if device is not a stack Member). Includes: • Stack Name • MAC Address • System Name • Status	Same as for Commander.	Same as for Commander.

Using Any Stacked Switch To View the Status for All Switches with Stacking Enabled. This procedure displays the general status of all switches in the IP subnet (broadcast domain) that have stacking enabled.

1. Go to the console Main Menu for any switch configured for stacking and select:

9. Stacking ...

2. Stacking Status (All)

You will then see a Stacking Status screen similar to the following:

For status descriptions, see the table on page 6-45.

Stack Name	MAC Address	System Name	Status
Big Waters	0060b0-880a80	Pacific Ocean	Commander Up
	0060b0-df1a00	Coral Sea	Member Up
	080009-8c5080	North Atlantic	Member Up
Newstack	001083-c3fc00	Newstack-0	Commander Up
	080009-918f80	Newstack-1	Member Up
	0060b0-df2a00	Newstack-2	Member Up
Others:	001083-3c09c0	DEFAULT_CONFIG	Candidate
	0060b0-e94300	DEFAULT_CONFIG	Candidate
	080009-918f80	DEFAULT_CONFIG	Candidate

Actions-> **Back** Next page Prev page Help

Return to previous screen.
Use up/down arrow keys to scroll to other entries, left/right arrow keys to change action selection, and <Enter> to execute action.

Figure 6-18. Example of Stacking Status for All Detected Switches Configured for Stacking

Viewing Commander Status. This procedure displays the Commander and stack configuration, plus information identifying each stack member.

To display the status for a Commander, go to the console Main Menu for the switch and select:

9. Stacking ...

1. Stacking Status (This Switch)

You will then see the Commander's Stacking Status screen:

```

Pacific Ocean
-----
----- CONSOLE - MANAGER MODE -----
Stacking - Stacking Status (This Switch)

Stack State      : Commander
Transmission Interval : 60
Stack Name       : Big_Waters Number of members      : 2
Auto Grab        : No Members unreachable           : 0

SN   MAC Address   System Name   Device Type   Status
-----
0    0060b0-880a80  Pacific Ocean   HP 2512       Commander Up
1    0060b0-df1a00  Coral Sea      3500yl       Member Up
2    080009-8c5080  North Atlantic  3500yl       Member Up

Actions->  Back      Help

Return to previous screen.
Use arrow keys to change action selection and <Enter> to execute action.

```

Figure 6-19. Example of the Commander's Stacking Status Screen

Viewing Member Status. This procedure displays the Member's stacking information plus the Commander's status, IP address, and MAC address.

To display the status for a Member:

1. Go to the console Main Menu of the Commander switch and select
 - 9. Stacking ...**
 - 5. Stack Access**
2. Use the downarrow key to select the Member switch whose status you want to view, then press **[X]** (for **eXecute**). You will then see the Main Menu for the selected Member switch.
3. In the Member's Main Menu screen, select
 - 9. Stacking ...**
 - 1. Stacking Status (This Switch)**

You will then see the Member's Stacking Status screen:

```
Coral Sea

----- TELNET - MANAGER MODE -----
Stacking - Stacking Status (This Switch)

Stack State           : Member
Transmission Interval : 60
Switch Number        : 1
Stack Name           : Big_Waters
Member Status        : Joined Successfully
Commander Status      : Commander Up
Commander IP Address  : 10.28.227.102
Commander MAC Address : 0060b0-880a80

Actions->  Back      Help

Return to previous screen.
Use arrow keys to change action selection and <Enter> to execute action.
```

Figure 6-20. Example of a Member's Stacking Status Screen

Viewing Candidate Status. This procedure displays the Candidate's stacking configuration.

To display the status for a Candidate:

1. Use Telnet (if the Candidate has a valid IP address for your network) or a direct serial port connection to access the menu interface Main Menu for the Candidate switch and select

9. Stacking ...

1. Stacking Status (This Switch)

You will then see the Candidate's Stacking Status screen:

```
Coral Sea

----- TELNET - MANAGER MODE -----
Stacking - Stacking Status (This Switch)

Stack State           : Candidate
Transmission Interval : 60
Auto Join            : No

Actions->  Back      Help

Return to previous screen.
Use arrow keys to change action selection and <Enter> to execute action.
```

Figure 6-21. Example of a Candidate's Stacking Screen

Using the CLI To View Stack Status and Configure Stacking

The CLI enables you to do all of the stacking tasks available through the menu interface.)

Table 6-6. CLI Commands for Configuring Stacking on a Switch

CLI Command	Operation
show stack [candidates view all]	Commander: Shows Commander's stacking configuration and lists the stack members and their individual status. Member: Lists Member's stacking configuration and status, and the status and the IP address and subnet mask of the stack Commander. Options: candidates: (Commander only) Lists stack Candidates. view: (Commander only) Lists current stack Members and their individual status. all: Lists all stack Commanders, Members and Candidates, with their individual status.
[no] stack	Any Stacking-Capable Switch: Enables or disables stacking on the switch. Default: Stacking Enabled
[no] stack commander <stack name>	Candidate or Commander: Converts a Candidate to a Commander or changes the stack name of an existing commander. "No" form eliminates named stack and returns Commander and stack Members to Candidate status with Auto Join set to No. "No" form prevents the switch from being discovered as a stacking-capable switch. Default: Switch Configured as a Candidate
[no] stack auto-grab	Commander: Causes Commander to automatically add to its stack any discovered Candidate in the subnet that does not have a Manager password and has Auto-Join set to Yes. Default: Disabled Note: If the Commander's stack already has 15 members, the Candidate cannot join until an existing member leaves the stack.

Stack Management

Configuring Stack Management

CLI Command	Operation
[no] stack member <switch-num> mac-address <mac-addr> [password <password-str>]	Commander: Adds a Candidate to stack membership. “No” form removes a Member from stack membership. To easily determine the MAC address of a Candidate, use the show stack candidates command. To determine the MAC address of a Member you want to remove, use the show stack view command. The password (<i>password-str</i>) is required only when adding a Candidate that has a Manager password.
telnet <1..15> <i>Used In:</i> Commander Only	Commander: Uses the SN (switch number— assigned by the stack Commander) to access the console interface (menu interface or CLI) of a stack member. To view the list of SN assignments for a stack, execute the show stack command in the Commander’s CLI.
[no] stack join <mac-addr>	Candidate: Causes the Candidate to join the stack whose Commander has the indicated MAC address. “No” form is used in a Member to remove it from the stack of the Commander having the specified address. Member: “Pushes” the member to another stack whose Commander has the indicated MAC address.
[no] stack auto-join	Candidate: Enables Candidate to automatically join the stack of any Commander in the IP subnet that has Auto Grab enabled, or disables Auto-Join in the candidate. Default: Auto Join enabled. Note: If the Candidate has a Manager password or if the available stack(s) already have the maximum of 15 Members, the automatic join will not occur.
stack transmission-interval	All Stack Members: specifies the interval in seconds for transmitting stacking discovery packets. Default: 60 seconds

Using the CLI To View Stack Status

You can list the stack status for an individual switch and for other switches that have been discovered in the same subnet.

Syntax: show stack [candidates | view | all]

Viewing the Status of an Individual Switch. The following example illustrates how to use the CLI in a to display the stack status for that switch. In this case, the switch is in the default stacking configuration.

Syntax: show stack

```
ProCurve(config)# show stack
Stacking - Stacking Status (This Switch)

Stack State           : Commander
Transmission Interval : 60
Stack Name            : Big_Waters           Number of members      : 1
Auto Grab             : Yes                  Members unreachable    : 0

SN MAC Address      System Name      Device Type  Status
-----
0  0030c1-7fcc40 3500yl      3500yl      Commander Up
1  0030c1-7fec40 piles-1      3500yl      Member Up
```

Figure 6-22. Example of Using the Show Stack Command To List the Stacking Configuration for an Individual Switch

Viewing the Status of Candidates the Commander Has Detected.

This example illustrates how to list stack candidates the Commander has discovered in the ip subnet (broadcast domain).

Syntax: show stack candidates

```
ProCurve(config)# show stack candidates
Stack Candidates
Candidate MAC System Name      Device Type
-----
0060b0-889e00 DEFAULT_CONFIG      3500yl
```

Figure 6-23. Example of Using the Show Stack Candidates Command To List Candidates

Viewing the Status of all Stack-Enabled Switches Discovered in the IP Subnet. The next example lists all the stack-configured switches discovered in the IP subnet. Because the switch on which the **show stack all** command was executed is a candidate, it is included in the “Others” category.

Syntax: show stack all

```
ProCurve (config)# show stack all
```

```
Stacking - Stacking Status (All)
```

Stack Name	MAC Address	System Name	Status
Big_Waters	0030c1-7fcc40	3500yl	Commander Up
	0030c1-7fec40	Big_Waters-1	Member Up
Others:	0060b0-889e00	DEFAULT_CONFIG	Candidate

Figure 6-24. Result of Using the Show Stack All Command To List Discovered Switches in the IP Subnet

Viewing the Status of the Commander and Current Members of the Commander’s Stack. The next example lists all switches in the stack of the selected switch.

Syntax: show stack view

```
ProCurve(config)# show stack view
```

```
Stack Members
```

SN	MAC Address	System Name	Device Type	Status
0	0030c1-7fcc40	3500yl	3500yl	Commander Up
1	0030c1-7fec40	Big_Waters-1	3500yl	Member Up

Figure 6-25. Example of the Show Stack View Command To List the Stack Assigned to the Selected Commander

Using the CLI To Configure a Commander Switch

You can configure any stacking-enabled switch to be a Commander as long as the intended stack name does not already exist on the broadcast domain. (When you configure a Commander, you automatically create a corresponding stack.)

Before you begin configuring stacking parameters:

1. Configure IP addressing on the switch intended for stack commander and, if not already configured, on the primary VLAN. (For more on configuring IP addressing, refer to the *Management and Configuration Guide* for your switch.)

Note

The primary VLAN must have an IP address in order for stacking to operate properly. For more on the primary VLAN, see “The Primary VLAN” on page 2-46.

2. Configure a Manager password on the switch intended for commander. (The Commander’s Manager password controls access to stack Members.) For more on passwords, see the local manager and operator password information in the *Access Security Guide* for your switch.

Configure the Stack Commander. Assigning a stack name to a switch makes it a Commander and automatically creates a stack.

Syntax: stack commander < name-str >

This example creates a Commander switch with a stack name of **Big_Waters**. (Note that if stacking was previously disabled on the switch, this command also enables stacking.)

```
ProCurve(config)# stack commander Big_Waters
```

As the following **show stack** display shows, the Commander switch is now ready to add members to the stack.

```
ProCurve(config)# show stack
Stacking - Stacking Status (This Switch)
Stack State           : Commander
Transmission Interval : 60
Stack Name            : Big_Waters
Auto Grab             : No
Number of members     : 0
Members unreachable   : 0

SN MAC Address      System Name      Device Type      Status
-----
0  0030c1-b24ac0    3500y1           3500y1           Commander Up
```

The **stack commander** command configures the Commander and names the stack.

The Commander appears in the stack as Switch Number (SN) 0.

Figure 6-26. Example of the Commander's Show Stack Screen with Only the Commander Discovered

Using a Member's CLI to Convert the Member to the Commander of a New Stack. This procedure requires that you first remove the Member from its current stack, then create the new stack. If you do not know the MAC address for the Commander of the current stack, use **show stack** to list it.

Syntax: no stack
 stack commander < stack name >

Suppose, for example, that a ProCurve switch named "Bering Sea" is a Member of a stack named "Big_Waters". To use the switch's CLI to convert it from a stack Member to the Commander of a new stack named "Lakes", you would use the following commands:

Figure 6-27. Example of Using a Member's CLI To Convert the Member to the Commander of a New Stack

Adding to a Stack or Moving Switches Between Stacks

You can add switches to a stack by adding discovered Candidates or by moving switches from other stacks that may exist in the same subnet. (You cannot add a Candidate that the Commander has not discovered.)

In its default configuration, the Commander's **Auto-Grab** parameter is set to **No** to give you manual control over which switches join the stack and when they join. This prevents the Commander from automatically trying to add every Candidate it finds that has **Auto Join** set to **Yes** (the default for the Candidate).

(If you want any eligible Candidate to automatically join the stack when the Commander discovers it, configure **Auto Grab** in the Commander to **Yes**. When you do so, *any* Candidate discovered with **Auto Join** set to **Yes** (the default) and no Manager password will join the stack, up to the limit of 15 Members.)

Using the Commander's CLI To Manually Add a Candidate to the Stack.

To manually add a candidate, you will use:

- A switch number (**SN**) to assign to the new member. Member SNs range from 1 to 15. To see which SNs are already assigned to Members, use **show stack view**. You can use any SN not included in the listing. (SNs are viewable only on a Commander switch.)
- The MAC address of the discovered Candidate you are adding to the stack. To see this data, use the **show stack candidates** listing.

For example:

```
ProCurve(config)# show stack view
Stack Members
```

SN	MAC Address	System Name	Device Type	Status
0	0030c1-7fec40	3500yl	3500yl	Commander Up
1	0060b0-880a80	Indian Ocean	3500yl	Member Up

In this stack, the only SNs in use are 0 and 1, so you can use any SN number from 2 through 15 for new Members. (The SN of "0" is always reserved for the stack Commander.)

Note: When manually adding a switch, you must assign an SN. However, if the Commander automatically adds a new Member, it assigns an SN from the available pool of unused SNs.

Figure 6-28. Example of How To Determine Available Switch Numbers (SNs)

To display all discovered Candidates with their MAC addresses, execute **show stack candidates** from the Commander's CLI. For example, to list the discovered candidates for the above Commander:

```
ProCurve(config)# show stack candidates
Stack Candidates
```

Candidate MAC	System Name	Device Type
0030c1-b24ac0	North Sea	3500yl
0060b0-dfla00	DEFAULT_CONFIG	3500yl

MAC addresses of discovered Candidates.

Figure 6-29. Example of How To Determine MAC Addresses of Discovered Candidates

Knowing the available switch numbers (**SNs**) and Candidate MAC addresses, you can proceed to manually assign a Candidate to be a Member of the stack:

Syntax: stack member < switch-number > mac-address < mac-addr >
[password < password-str >]

For example, if the switch in the above listing did not have a Manager password and you wanted to make it a stack Member with an **SN** of **2**, you would execute the following command:

```
ProCurve(config)# stack member 2 mac-address 0060b0-dfla00
```

The **show stack view** command then lists the Member added by the above command:

```
ProCurve(config)# show stack view
Stack Members
```

SN	MAC Address	System Name	Device Type	Status
0	0030c1-7fec40	3500yl	3500yl	Commander Up
1	0060b0-880a80	Indian Ocean	3500yl	Member Up
2	0060b0-dfla00	Big_Waters-2	3500yl	Member Up

SN (Switch Number) 2 is the new Member added by the **stack member** command.

The new member did not have a System Name configured prior to joining the stack, and so receives a System Name composed of the stack name (assigned in the Commander) with its SN number as a suffix.

Figure 6-30. Example Showing the Stack After Adding a New Member

Using Auto Join on a Candidate. In the default configuration, a Candidate's Auto Join parameter is set to "Yes", meaning that it will automatically join a stack if the stack's Commander detects the Candidate and the Commander's Auto Grab parameter is set to "Yes". You can disable Auto Join on a Candidate if you want to prevent automatic joining in this case. There is also the instance where a Candidate's Auto Join is disabled, for example, when a Commander leaves a stack and its members automatically return to Candidate status, or if you manually remove a Member from a stack. In this case, you may want to reset Auto Join to "Yes".

Status: **[no] stack auto-join**

```
ProCurve(config)# no stack auto-join
Disables Auto Join on a Candidate.
```

```
ProCurve(config)# stack auto-join
Enables Auto Join on a Candidate.
```

Using a Candidate CLI To Manually "Push" the Candidate Into a Stack . Use this method if any of the following apply:

- The Candidate's **Auto Join** is set to **Yes** (and you do not want to enable **Auto Grab** on the Commander) or the Candidate's **Auto Join** is set to **No**.
- Either you know the MAC address of the Commander for the stack into which you want to insert the Candidate, or the Candidate has a valid IP address and is operating in your network.

Syntax: `stack join < mac-addr >`

where: **< mac-addr >** is the MAC address of the Commander in the destination stack.

Use Telnet (if the Candidate has an IP address valid for your network) or a direct serial port connection to access the CLI for the Candidate switch. For example, suppose that a Candidate named “North Sea” with **Auto Join** off and a valid IP address of 10.28.227.104 is running on a network. You could Telnet to the Candidate, use **show stack all** to determine the Commander's MAC address, and then “push” the Candidate into the desired stack.

Figure 6-31. Example of “Pushing” a Candidate Into a Stack

To verify that the Candidate successfully joined the stack, execute **show stack all** again to view the stacking status.

Using the Destination Commander CLI To “Pull” a Member from Another Stack. This method uses the Commander in the destination stack to “pull” the Member from the source stack.

Syntax: stack member < switch-number >
 mac-address < mac-addr >
 [password < password-str >]

In the destination Commander, use **show stack all** to find the MAC address of the Member you want to pull into the destination stack. For example, suppose you created a new Commander with a stack name of “Cold_Waters” and you wanted to move a switch named “Bering Sea” into the new stack:

```
ProCurve(config)# show stack all
Stacking - Stacking Status (All)
```

Stack Name	MAC Address	System Name	Status

Big_Waters	0030c1-7fec40	3500yl	Commander Up
	0060b0-880a80	Indian Ocean	Member Up
	0060b0-df1a00	Bering Sea	Member Up
Cold_Waters	0030c1-7fc700	3500yl	Commander Up

Move this switch into the “Cold Waters” stack.

Figure 6-32. Example of Stack Listing with Two Stacks in the Subnet

You would then execute the following command to pull the desired switch into the new stack:

```
ProCurve(config)# stack member 1 mac-address 0060b0-df1a00
```

Where **1** is an unused switch number (**SN**).

Since a password is not set on the Candidate, a password is not needed in this example.

You could then use **show stack all** again to verify that the move took place.

Using a Member CLI To “Push” the Member into Another Stack. You can use the Member’s CLI to “push” a stack Member into a destination stack if you know the MAC address of the destination Commander.

Syntax: stack join <mac-addr>

where: < mac-addr > is the MAC address of the Commander for the destination stack.

Converting a Commander to a Member of Another Stack. Removing the Commander from a stack eliminates the stack and returns its Members to the Candidate pool with **Auto Join** disabled.

Syntax: no stack name <stack name>
stack join <mac-address>

If you don't know the MAC address of the destination Commander, you can use **show stack all** to identify it.

For example, suppose you have a switch operating as the Commander for a temporary stack named "Test". When it is time to eliminate the temporary "Test" stack and convert the switch into a member of an existing stack named "Big_Waters", you would execute the following commands in the switch's CLI:

```
ProCurve(config)# no stack name Test
ProCurve(config)# show stack all
Stacking - Stacking Status (All)
Stack Commander  MAC Address  System Name  Status
-----
Big_Waters       0030c1-7fc700  3500yl       Commander Up
                  0060b0-889e00  Big_Waters-1  Member Up
Others:          0030c1-7fec40  3500yl       Candidate
ProCurve(config)# stack join 0030c1-7fc700
```

Eliminates the "Test" stack and converts the Commander to a Candidate.

Helps you to identify the MAC address of the Commander for the "Big_Waters" stack.

Adds the former "Test" Commander to the "Big_Waters" stack.

Figure 6-33. Example of Command Sequence for Converting a Commander to a Member

Using the CLI To Remove a Member from a Stack

You can remove a Member from a stack using the CLI of either the Commander or the Member.

Note

When you remove a Member from a stack, the Member's **Auto Join** parameter is set to **No**.

Using the Commander CLI To Remove a Stack Member. This option requires the switch number (SN) and the MAC address of the switch to remove. (Because the Commander propagates its Manager password to all stack members, knowing the Manager password is necessary only for gaining access to the Commander.)

Syntax: [no] stack member <switch-num> mac-address <mac-addr>

Use **show stack view** to list the stack Members. For example, suppose that you wanted to use the Commander to remove the “North Sea” Member from the following stack:

ProCurve (config)# show stack view					
Stack Members					
	SN	MAC Address	System Name	Device Type	Status

Remove this Member from the stack.	0	0030c1-7fec40	3500yl	3500yl	Commander Up
	1	0060b0-880a80	Indian Ocean	3500yl	Member Up
	2	0060b0-df1a00	Bering Sea	3500yl	Member Up
	3	0030c1-7fc700	North Sea	3500yl	Member Up

Figure 6-34. Example of a Commander and Three Switches in a Stack

You would then execute this command to remove the “North Sea” switch from the stack:

```
ProCurve(config)# no stack member 3 mac-address 0030c1-7fc700
```

where:

- **3** is the “North Sea” Member’s switch number (**SN**)
- **0030c1-7fc700** is the “North Sea” Member’s MAC address

Using the Member’s CLI To Remove the Member from a Stack.

Syntax: no stack join <mac-addr>

To use this method, you need the Commander’s MAC address, which is available using the show stack command in the Member’s CLI. For example:

CLI for “North Sea” Stack Member	North Sea(config)# show stack
	Stacking - Stacking Status (This Switch)
	Stack State : Member
	Transmission Interval : 10
	Switch Number : 3
	Stack Name : Big_Waters
MAC Address of the Commander for the Stack to Which the “North Sea” Switch Belongs	Member Status : Joined Successfully
	Commander Status : Commander Up
	Commander IP Address : 10.28.227.103
	Commander MAC Address : 0030c1-7fec40

Figure 6-35. Example of How To Identify the Commander’s MAC Address from a Member Switch

You would then execute this command in the “North Sea” switch’s CLI to remove the switch from the stack:

```
North Sea(config)# no stack join 0030c1-7fec40
```

Using the CLI To Access Member Switches for Configuration Changes and Traffic Monitoring

After a Candidate becomes a Member, you can use the telnet command from the Commander to access the Member’s CLI or console interface for the same configuration and monitoring that you would do through a Telnet or direct-connect access from a terminal.

Syntax: telnet <switch-number>

where: unsigned integer is the switch number (**SN**) assigned by the Commander to each member (range: **1 - 15**).

To find the switch number for the Member you want to access, execute the **show stack view** command in the Commander’s CLI. For example, suppose that you wanted to configure a port trunk on the switch named “North Sea” in the stack named “Big_Waters”. Do do so you would go to the CLI for the “Big_Waters” Commander and execute show stack view to find the switch number for the “North Sea” switch:

```
ProCurve(config)# show stack view
Stack Members
```

SN	MAC Address	System Name	Device Type	Status
0	0030c1-7fec40	3500y1	3500y1	Commander Up
1	0060b0-880a80	Indian Ocean	3500y1	Member Up
2	0060b0-df1a00	Bering Sea	3500y1	Member Up
3	0030c1-7fc700	North Sea	3500y1	Member Up

Figure 6-36. Example of a Stack Showing Switch Number (SN) Assignments

To access the “North Sea” console, you would then execute the following **telnet** command:

```
ProCurve(config)# telnet 3
```

You would then see the CLI prompt for the “North Sea” switch, allowing you to configure or monitor the switch as if you were directly connected to the console.

SNMP Community Operation in a Stack

Community Membership

In the default stacking configuration, when a Candidate joins a stack, it automatically becomes a Member of any SNMP community to which the Commander belongs, even though any community names configured in the Commander are not propagated to the Member's SNMP Communities listing. However, if a Member has its own (optional) IP addressing, it can belong to SNMP communities to which other switches in the stack, including the Commander, do not belong. For example:

Figure 6-37. Example of SNMP Community Operation with Stacking

SNMP Management Station Access to Members Via the Commander.

To use a management station for SNMP Get or Set access through the Commander's IP address to a Member, you must append **@sw<switch number>** to the community name. For example, in figure 6-37, you would use the following command in your management station to access Switch 1's MIB using the blue community:

```
snmpget <MIB variable> 10.31.29.100 blue@sw1
```

Note that because the gray community is only on switch 3, you could not use the Commander IP address for gray community access from the management station. Instead, you would access switch 3 directly using the switch's own IP address. For example:

```
snmpget <MIB variable> 10.31.29.15 gray
```

Note that in the above example (figure 6-37) you cannot use the public community through the Commander to access any of the Member switches. For example, you can use the public community to access the MIB in switches 1 and 3 by using their unique IP addresses. However, you must use the red or blue community to access the MIB for switch 2.

```
snmpget < MIB variable > 10.31.29.100 blue@sw2
```

Using the CLI To Disable or Re-Enable Stacking

In the default configuration, stacking is enabled on the switch. You can use the CLI to disable stacking on the switch at any time. Disabling stacking has the following effects:

- **Disabling a Commander:** Eliminates the stack, returns the stack Members to Candidates with **Auto Join** disabled, and changes the Commander to a stand-alone (nonstacking) switch. You must re-enable stacking on the switch before it can become a Candidate, Member, or Commander.
- **Disabling a Member:** Removes the Member from the stack and changes it to a stand-alone (nonstacking) switch. You must re-enable stacking on the switch before it can become a Candidate, Member, or Commander.
- **Disabling a Candidate:** Changes the Candidate to a stand-alone (nonstacking) switch.

Syntax: no stack (*Disables stacking on the switch.*)
 stack (*Enables stacking on the switch.*)

Transmission Interval

All switches in the stack must be set to the same transmission interval to help ensure proper stacking operation. HP recommends that you leave this parameter set to the default 60 seconds.

Syntax: stack transmission-interval < seconds >

Stacking Operation with Multiple VLANs Configured

Stacking uses the primary VLAN in a switch. In the factory-default configuration, the DEFAULT_VLAN is the primary VLAN. However, you can designate any VLAN configured in the switch as the primary VLAN. (See “The Primary VLAN” on page 2-46.)

When using stacking in a multiple-VLAN environment, the following criteria applies:

- Stacking uses only the primary VLAN on each switch in a stack.
- The primary VLAN can be tagged or untagged as needed in the stacking path from switch to switch.
- The same VLAN ID (VID) must be assigned to the primary VLAN in each stacked switch.

Status Messages

Stacking screens and listings display these status messages:

Message	Condition	Action or Remedy
Candidate Auto-join	Indicates a switch configured with Stack State set to Candidate , Auto Join set to Yes (the default), and no Manager password.	None required
Candidate	Candidate cannot automatically join the stack because one or both of the following conditions apply: • Candidate has Auto Join set to No. • Candidate has a Manager password.	Manually add the candidate to the stack.
Commander Down	Member has lost connectivity to its Commander.	Check connectivity between the Commander and the Member.
Commander Up	The Member has stacking connectivity with the Commander.	None required.
Mismatch	This may be a temporary condition while a Candidate is trying to join a stack. If the Candidate does not join, then stack configuration is inconsistent.	Initially, wait for an update. If condition persists, reconfigure the Commander or the Member.
Member Down	A Member has become detached from the stack. A possible cause is an interruption to the link between the Member and the Commander.	Check the connectivity between the Commander and the Member.
Member Up	The Commander has stacking connectivity to the Member.	None required.
Rejected	The Candidate has failed to be added to the stack.	The candidate may have a password. In this case, manually add the candidate. Otherwise, the stack may already be full. A stack can hold up to 15 Members (plus the Commander).
